CRASH RECOVERY

Recovery algorithms are techniques to ensure database consistency, transaction atomicity, and durability despite failures.

Recovery algorithms have two parts:

- Actions during normal txn processing to ensure that the DBMS can recover from a failure.
- Actions after a failure to recover the database to a state that ensures atomicity, consistency, and durability.

Today

ARIES

Algorithms for Recovery and Isolation Exploiting Semantics

Developed at IBM Research in early 1990s.

Not all systems implement ARIES exactly as defined in this paper but they're close.

ARIES: A Transaction Recovery Method Supporting Fine-Granularity Locking and Partial Rollbacks Using Write-Ahead Logging

C. MOHAN

IBM Almaden Research Center

In this paper we present a simple and efficient method, called ARIES (*Algorithm for Recovery and Isolation Exploiting Semantics*), which supports partial rollbacks of transactions, fine-granularity (e.g., record) locking and recovery using write-ahead logging (WAL). We introduce the paradigm of *repeating history* to redo all missing updates *before* performing the rollbacks of the loser transactions during restart after a system failure. ARIES uses a log sequence number in each page to correlate the state of a page with respect to logged updates of that page. All updates of a transaction are logged, including those performed during rollbacks. By appropriate chaining of the log records written during rollbacks to those written during forward progress, a bounded amount of logging is ensured during rollbacks even in the face of repeated failures during restart or of nested rollbacks. We deal with a variety of features that are very important in building and operating an *industrial-strength* transaction processing system. ARIES supports fuzzy checkpoints, selective and deferred restart, fuzzy image copies, media recovery, and high concurrency lock modes (e.g., increment/decrement) which exploit the semantics of the operations and require the ability to perform operation logging. ARIES is flexible with respect to the kinds of buffer management policies that can be implemented. It supports objects of varying length efficiently. By enabling parallelism during restart, page-oriented redo, and logical undo, it enhances concurrency and performance. We show why some of the System R paradigms for logging and recovery, which were based on the shadow page technique, need to be changed in the context of WAL. We compare ARIES to the WAL-based recovery methods of

ARIES – MAIN IDEAS

Write-Ahead Logging:

- Any change is recorded in log on stable storage before the database change is written to disk.
- Has to be **STEAL** + **NO-FORCE**.

Repeating History During Redo:

- On restart, retrace actions and restore database to exact state before crash.

Logging Changes During Undo:

- Record undo actions to log to ensure action is not repeated in the event of repeated failures.

TODAY'S AGENDA

Log Sequence Numbers

Normal Commit & Abort Operations

Fuzzy Checkpointing

Recovery Algorithm

WAL RECORDS

We need to extend our log record format from last class to include additional info.

Every log record now includes a globally unique *log sequence number* (LSN).

Various components in the system keep track of *LSNs* that pertain to them...

LOG SEQUENCE NUMBERS

Name	Where	Definition
flushedLSN	Memory	Last LSN in log on disk
pageLSN	page _x	Newest update to page _x
recLSN	page _x	Oldest update to page _x since it was last flushed
lastLSN	T _i	Latest action of txn T _i
MasterRecord	Disk	LSN of latest checkpoint

WRITING LOG RECORDS

Each data page contains a **pageLSN**.

→ The *LSN* of the most recent update to that page.

System keeps track of **flushedLSN**.

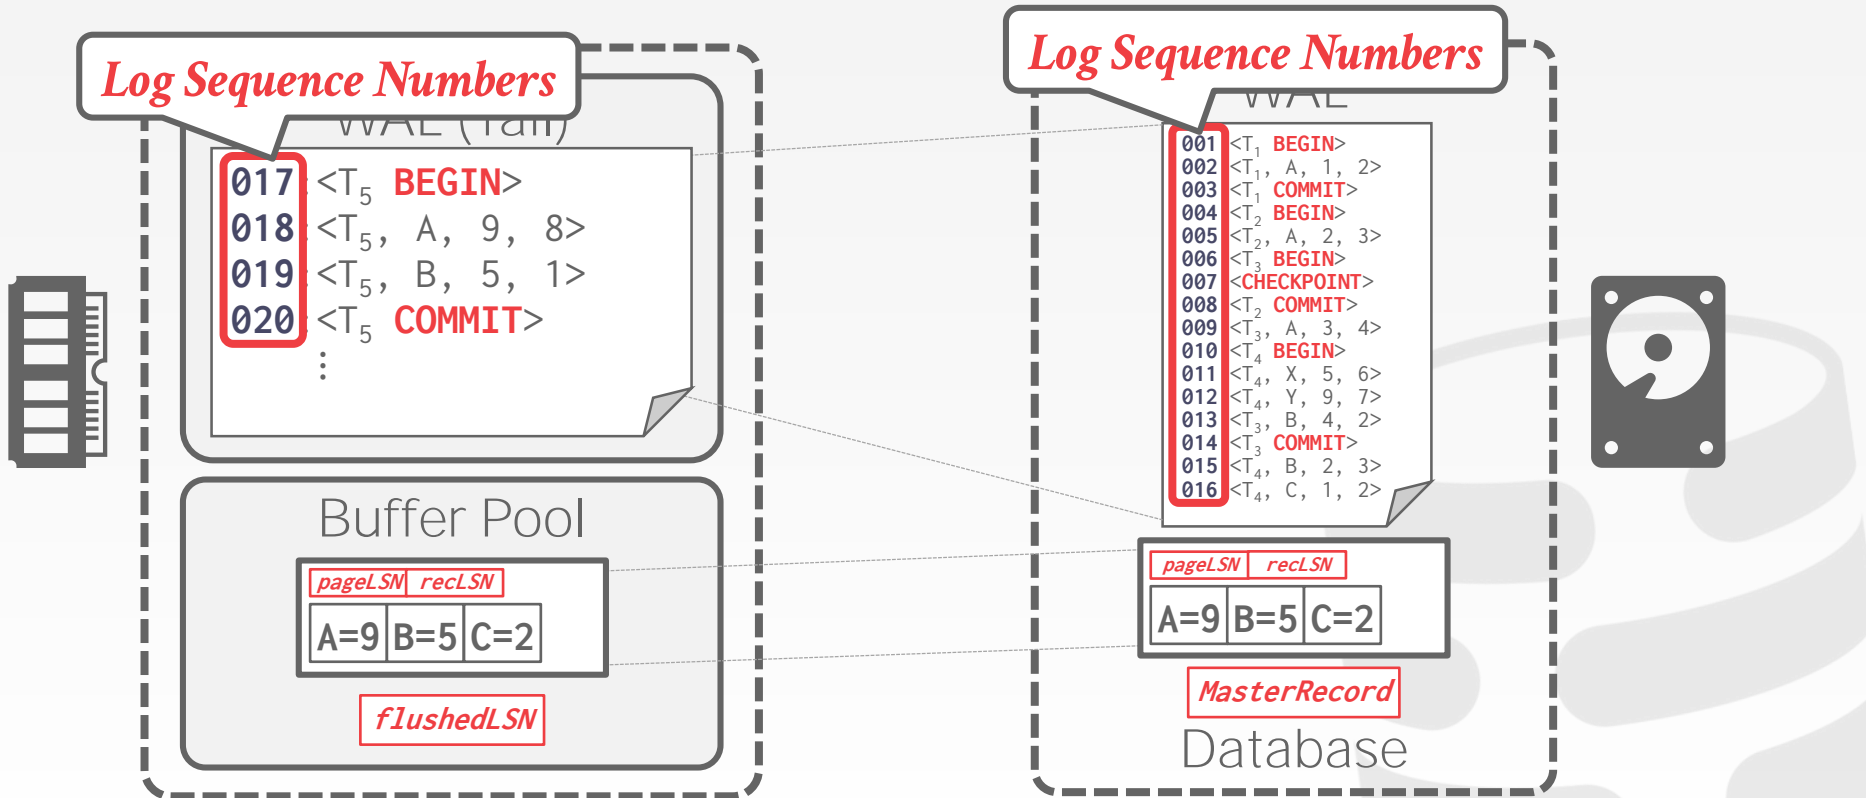

→ The max *LSN* flushed so far.

Before page **x** can be written to disk, we must flush log at least to the point where:

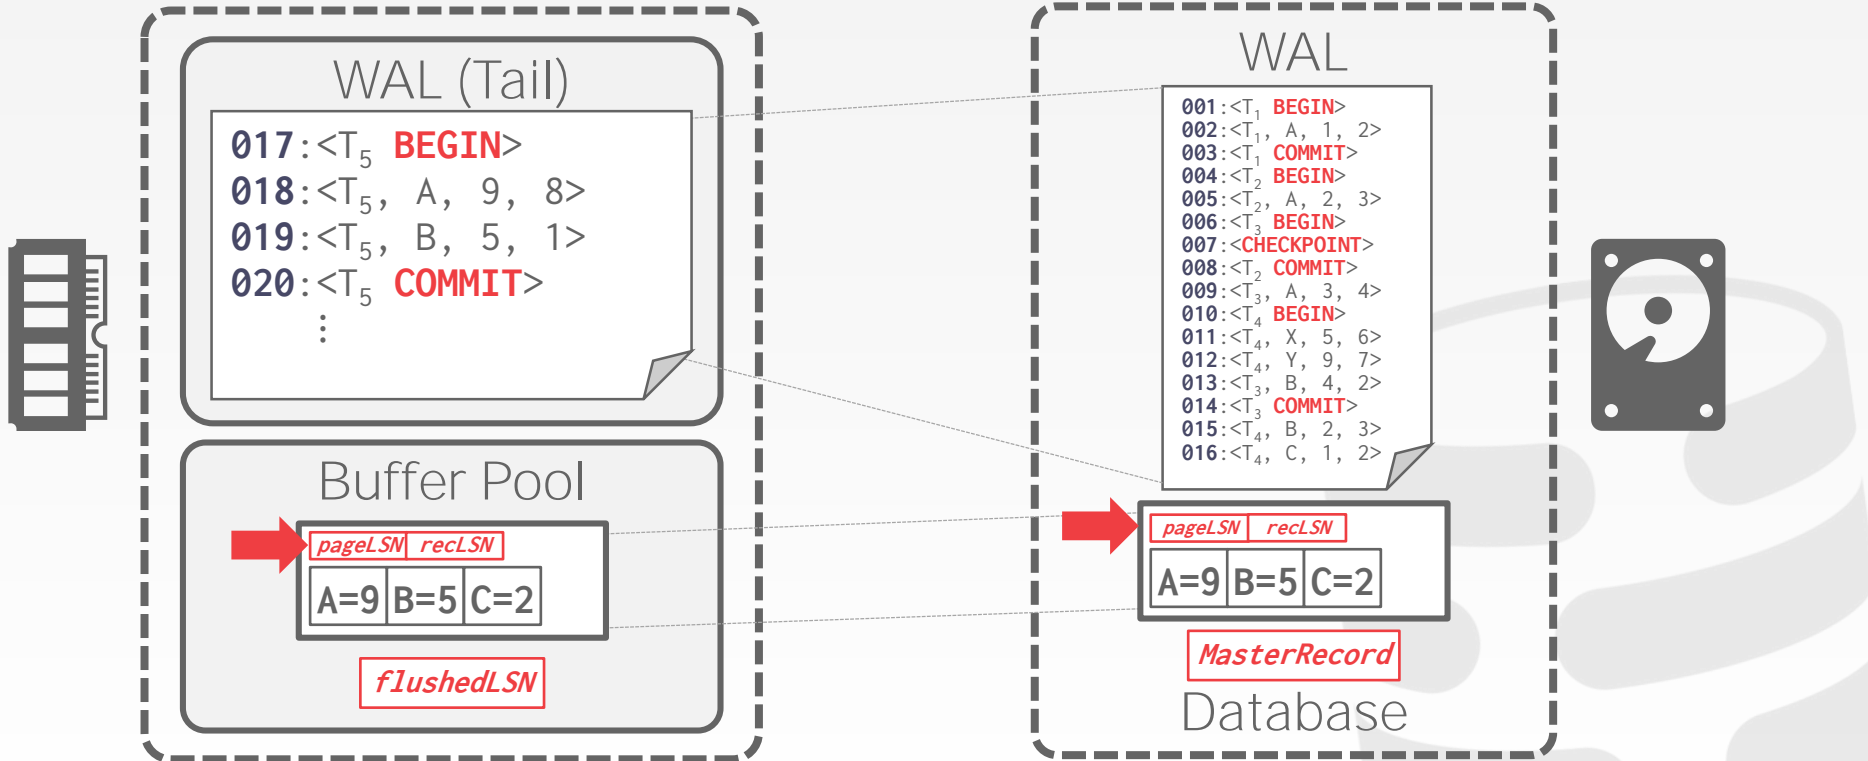

→ **$\text{pageLSN}_x \leq \text{flushedLSN}$**

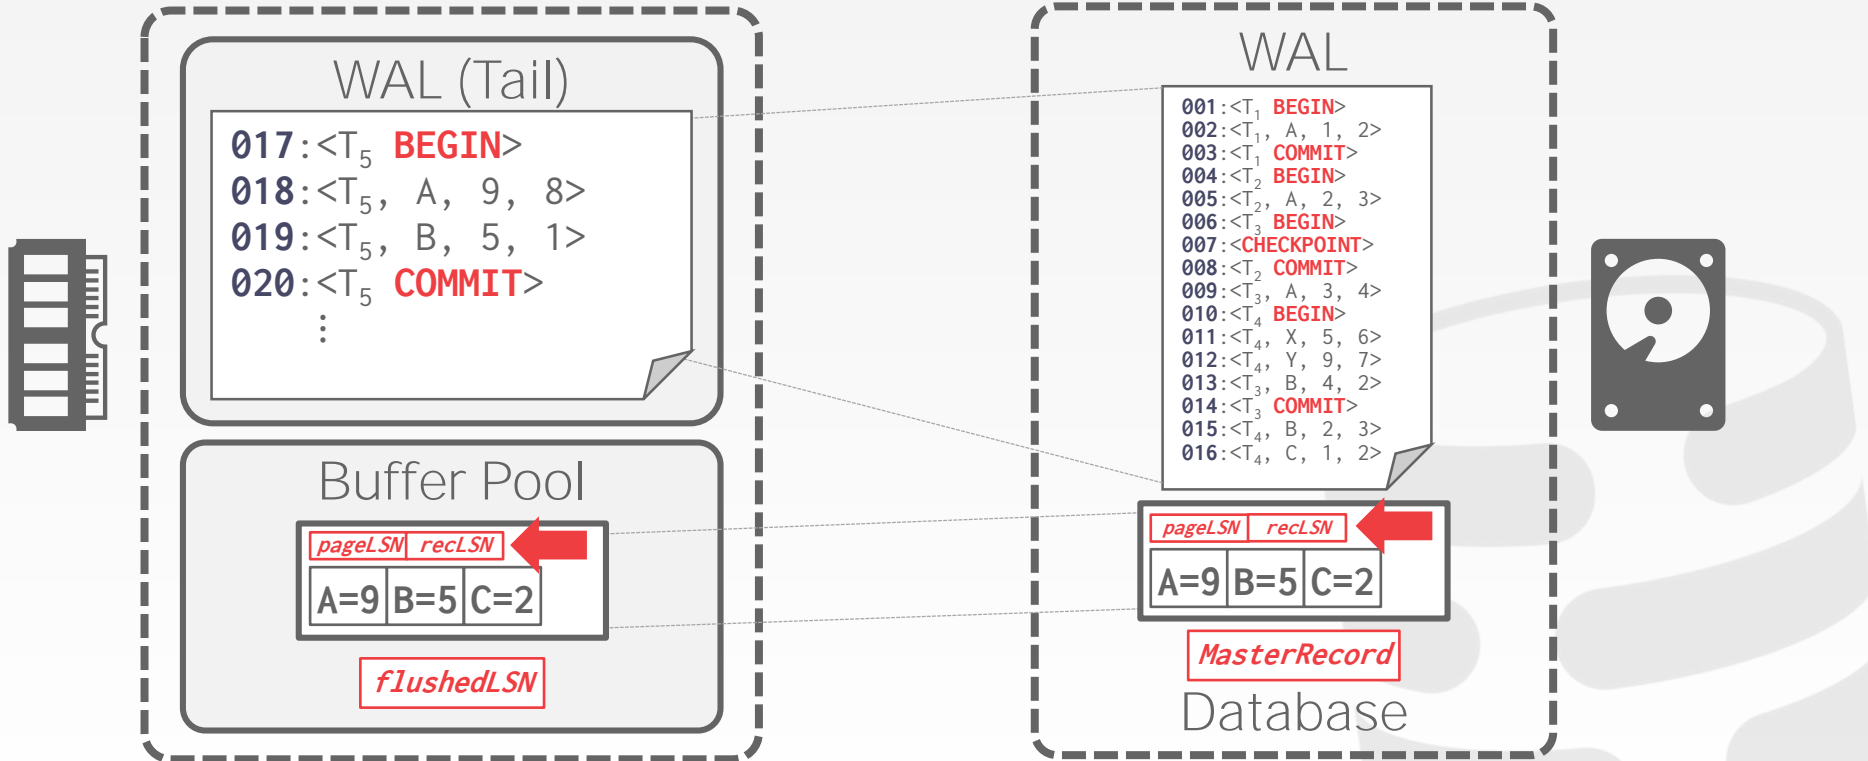

WRITING LOG RECORDS

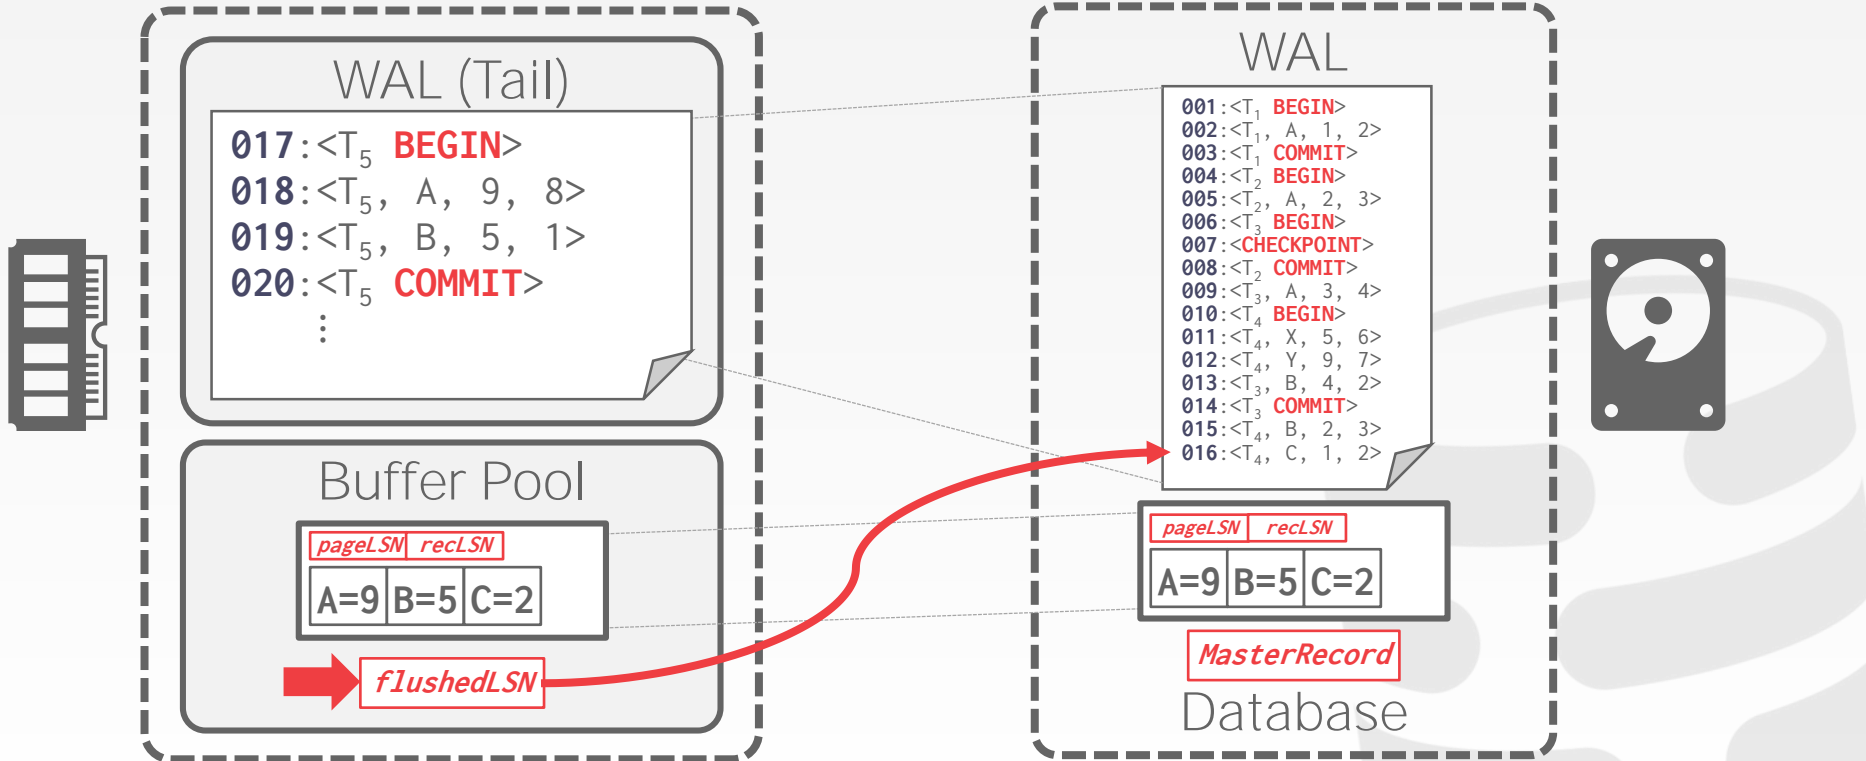

WRITING LOG RECORDS

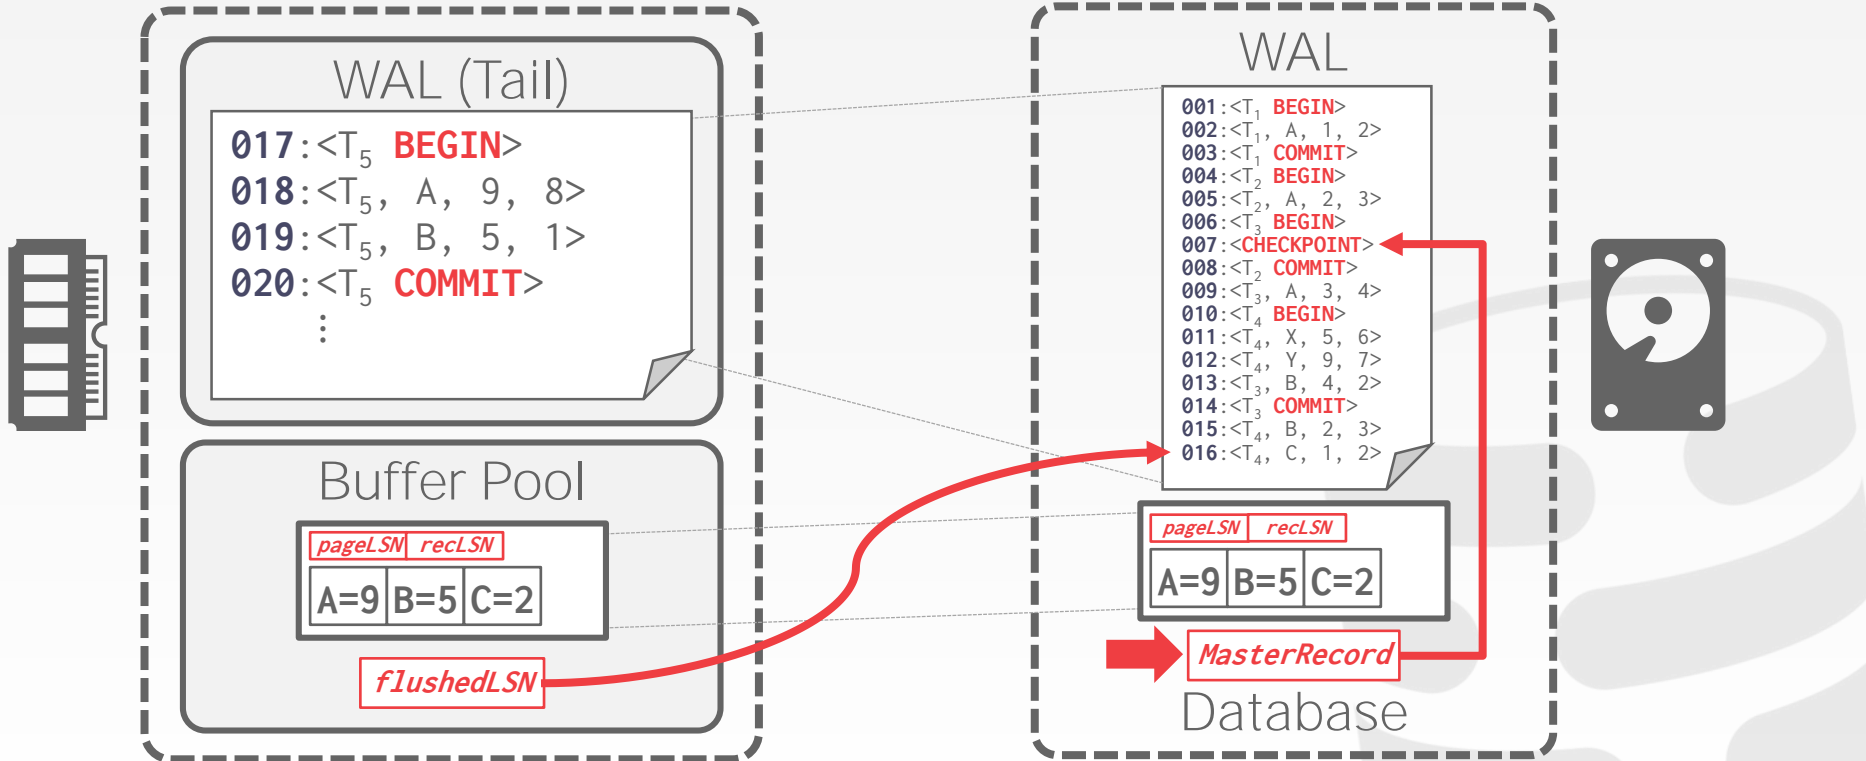

WRITING LOG RECORDS

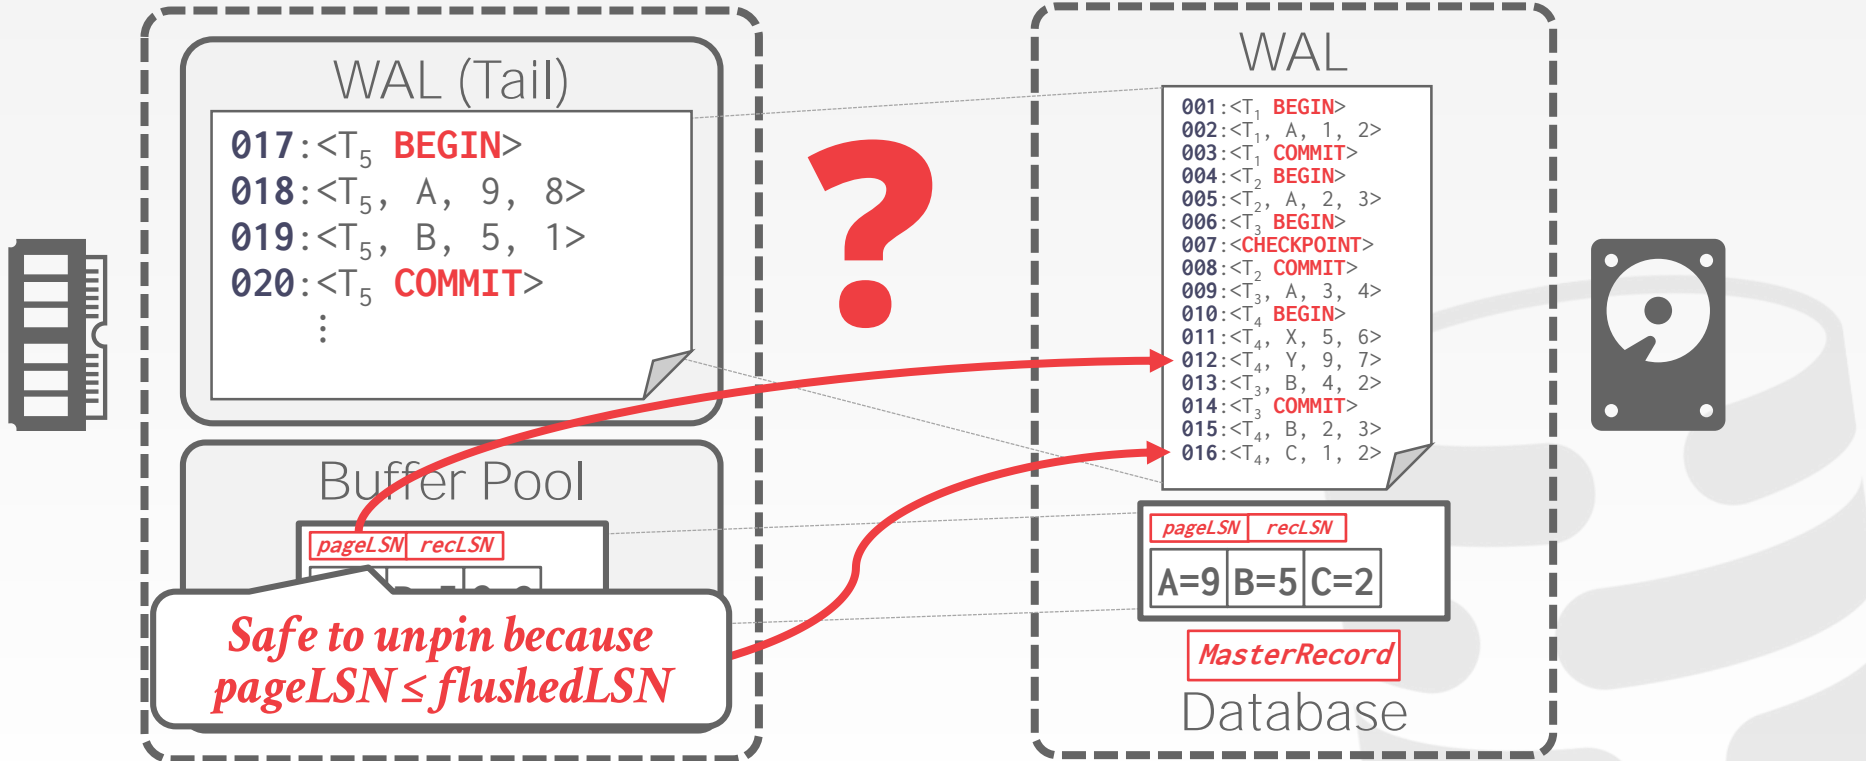

WRITING LOG RECORDS

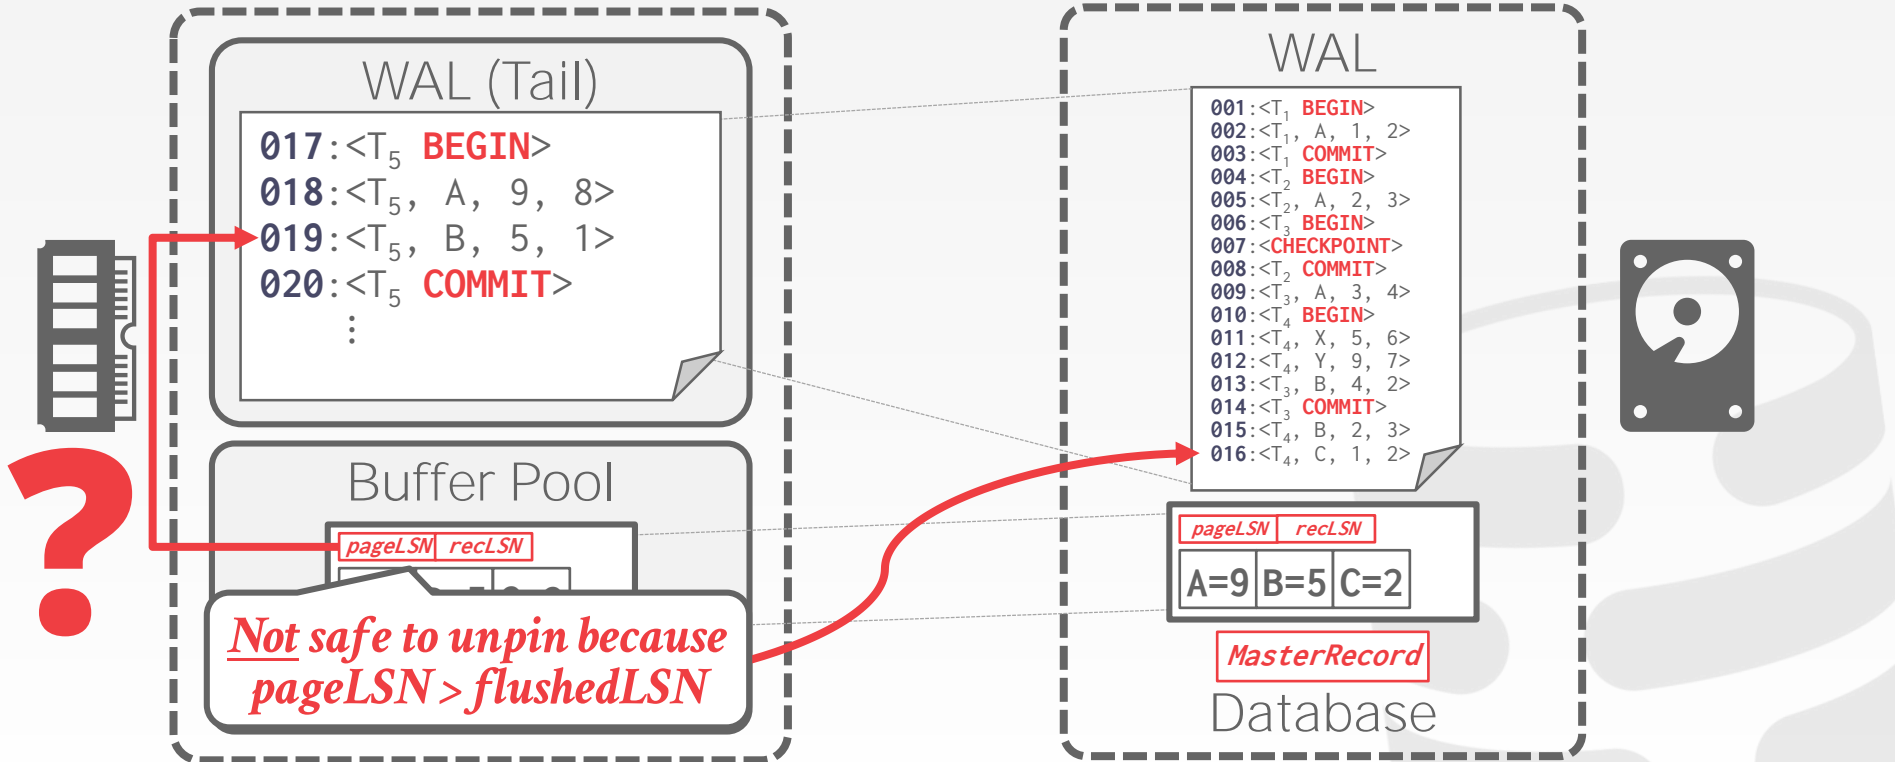

WRITING LOG RECORDS

WRITING LOG RECORDS

WRITING LOG RECORDS

WRITING LOG RECORDS

All log records have an *LSN*.

Update the **pageLSN** every time a txn modifies a record in the page.

Update the **flushedLSN** in memory every time the DBMS writes out the WAL buffer to disk.

NORMAL EXECUTION

Each txn invokes a sequence of reads and writes, followed by commit or abort.

Assumptions in this lecture:

- All log records fit within a single page.
- Disk writes are atomic.
- Single-versioned tuples with Strict 2PL.
- **STEAL** + **NO-FORCE** buffer management with WAL.

TRANSACTION COMMIT

Write **COMMIT** record to log.

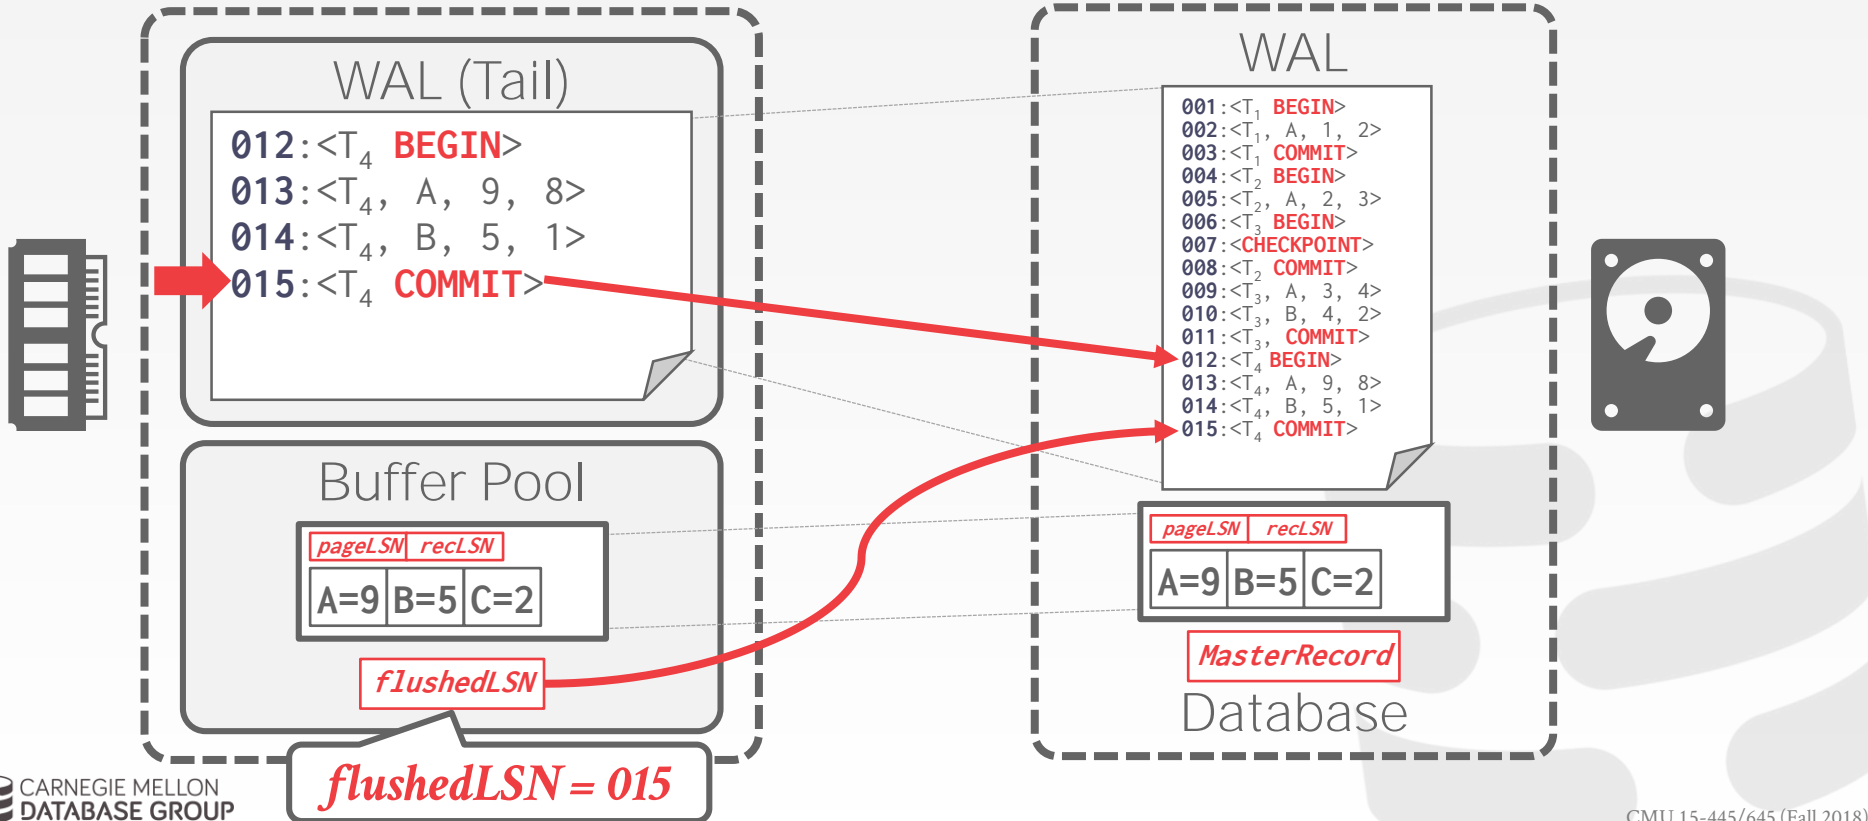

All log records up to txn's **COMMIT** record are flushed to disk.

- Note that log flushes are sequential, synchronous writes to disk.
- Many log records per log page.

When the commit succeeds, write a special **TXN-END** record to log.

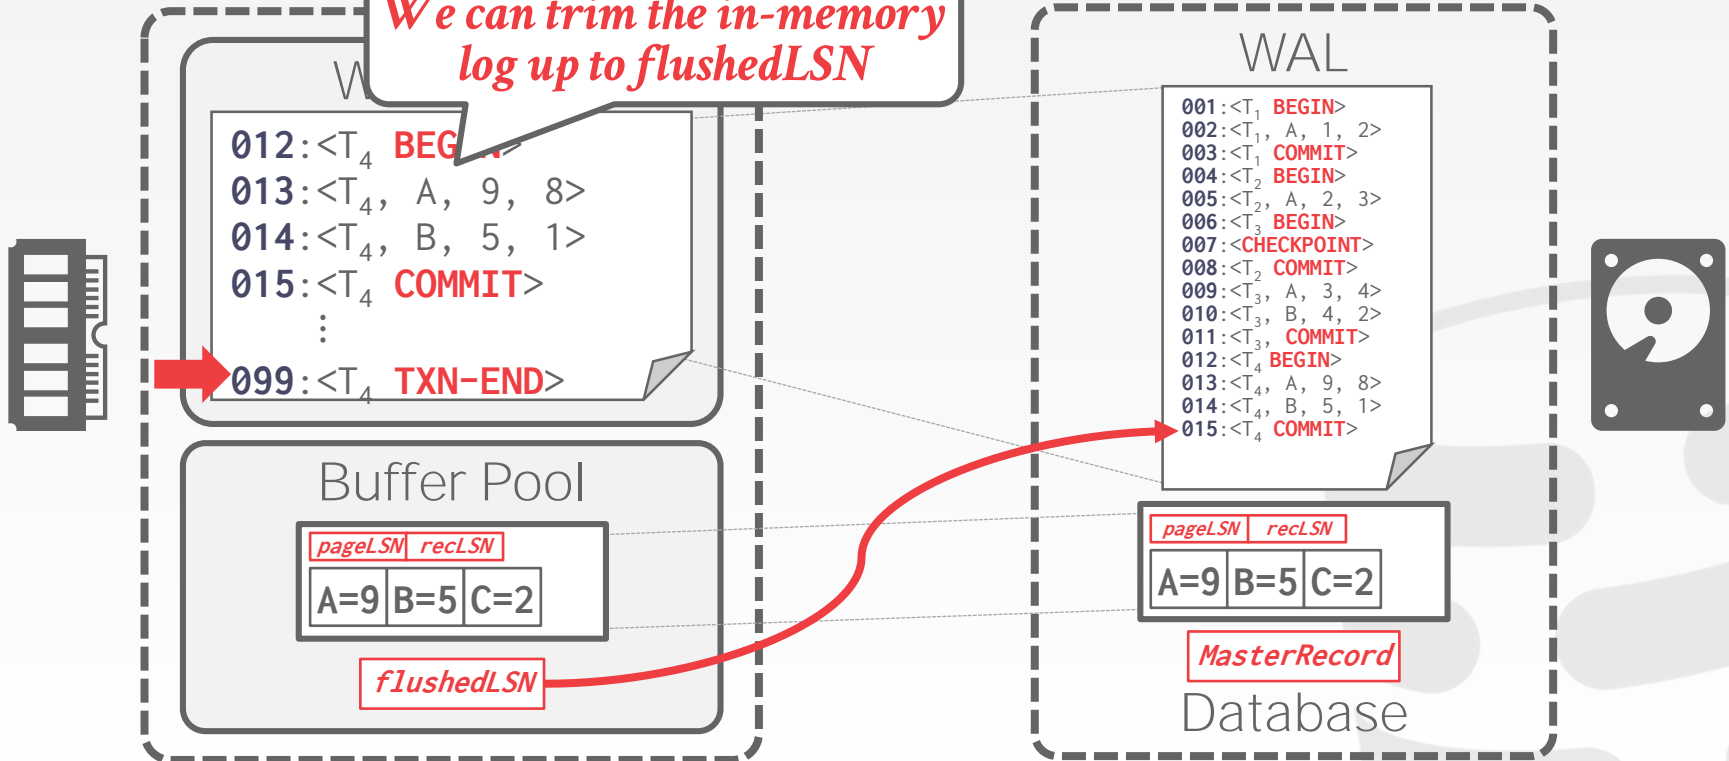

- This does not need to be flushed immediately.

TRANSACTION COMMIT

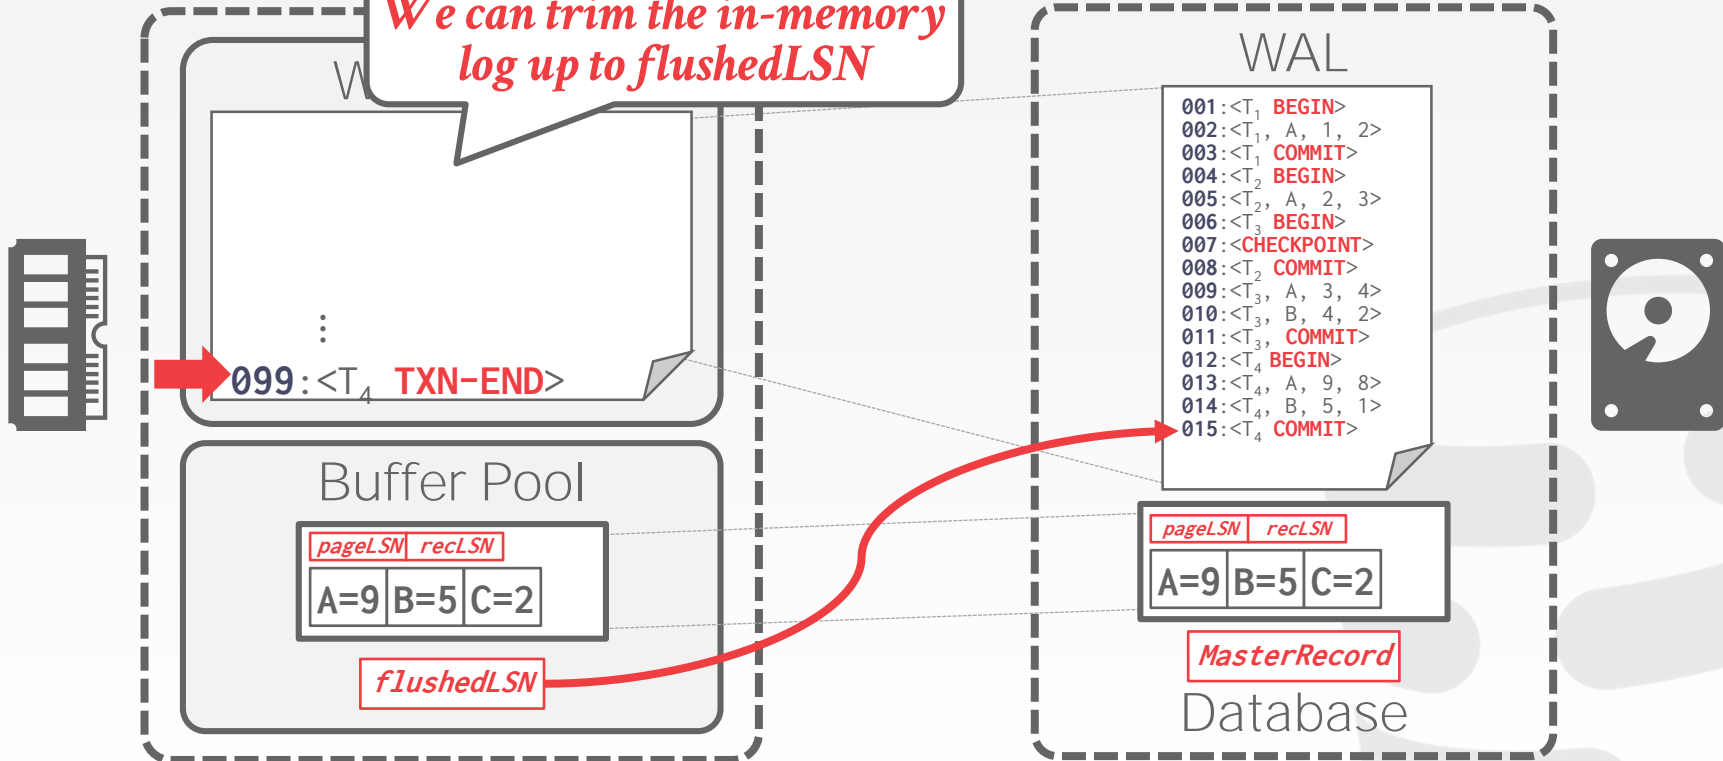

TRANSACTION COMMIT

We can trim the in-memory log up to flushedLSN

TRANSACTION COMMIT

We can trim the in-memory log up to flushedLSN

TRANSACTION ABORT

Aborting a txn is actually a special case of the ARIES undo operation applied to only one transaction.

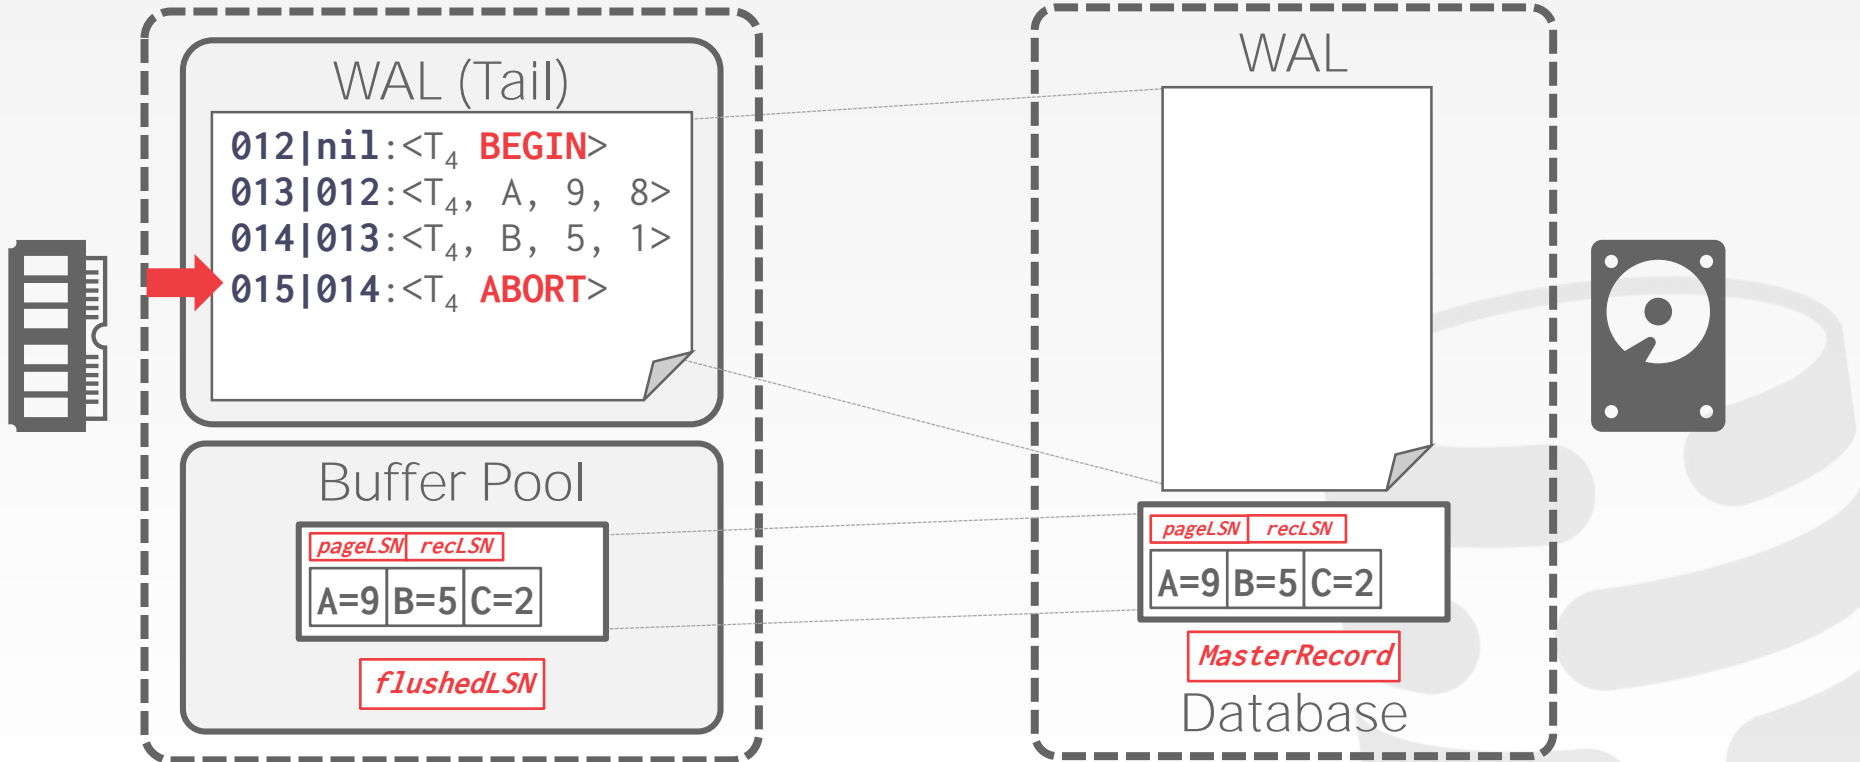

We need to add another field to our log records:

- **prevLSN**: The previous *LSN* for the txn.
- This maintains a linked-list for each txn that makes it easy to walk through its records.

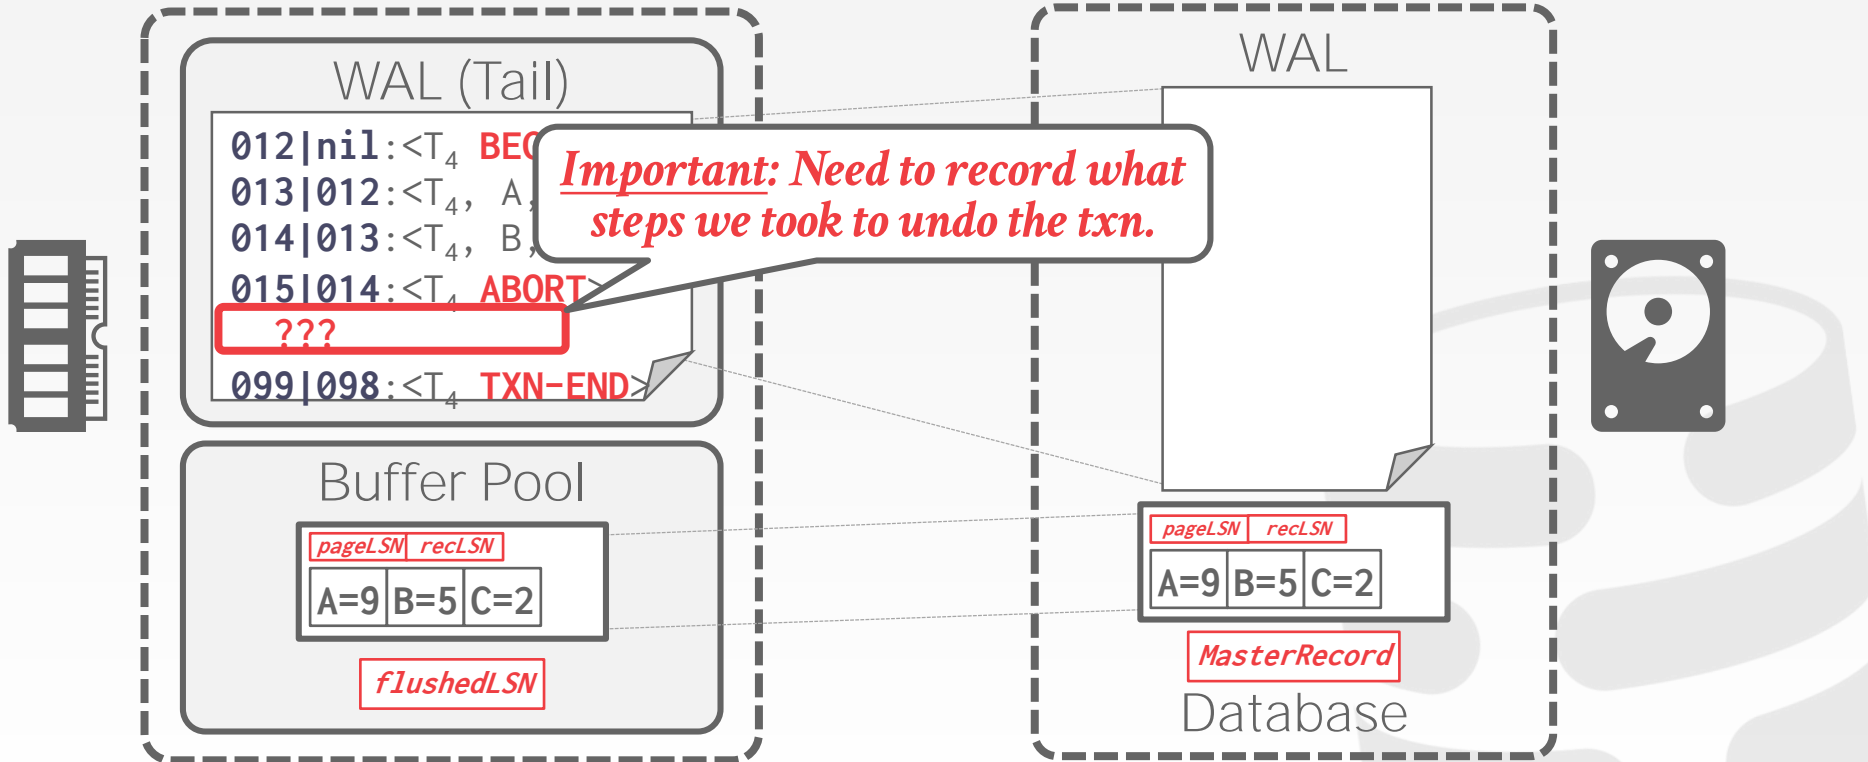

TRANSACTION COMMIT

TRANSACTION COMMIT

TRANSACTION COMMIT

COMPENSATION LOG RECORDS

A **CLR** describes the actions taken to undo the actions of a previous update record.

It has all the fields of an update log record plus the **undoNext** pointer (the next-to-be-undone LSN).

CLRs are added to log like any other record.

TRANSACTION ABORT – CLR EXAMPLE

LSN	prevLSN	TxnId	Type	Object	Before	After	UndoNext
001	nil	T_1	BEGIN	-	-	-	-
002	001	T_1	UPDATE	A	30	40	-
⋮							
011	002	T_1	ABORT	-	-	-	-

TRANSACTION ABORT – CLR EXAMPLE

LSN	prevLSN	TxnId	Type	Object	Before	After	UndoNext
001	nil	T ₁	BEGIN	-	-	-	-
002	001	T ₁	UPDATE	A	30	40	-
⋮							
011	002	T ₁	ABORT	-	-	-	-
⋮							
026	011	T ₁	CLR	A	40	30	001

TRANSACTION ABORT – CLR EXAMPLE

LSN	prevLSN	TxnId	Type	Object	Before	After	UndoNext
001	nil	T ₁	BEGIN	-	-	-	-
002	001	T ₁	UPDATE	A	30	40	-
⋮							
011	002	T ₁	ABORT	-	-	-	-
⋮							
026	011	T ₁	CLR	A	40	30	001

TRANSACTION ABORT – CLR EXAMPLE

LSN	prevLSN	TxnId	Type	Object	Before	After	UndoNext
001	nil	T ₁	BEGIN	-	-	-	-
002	001	T ₁	UPDATE	A	30	40	-
⋮							
011	002	T ₁	ABORT	-	-	-	-
⋮							
026	011	T ₁	CLR	A	40	30	001

The LSN of the next log record to be undone.

TRANSACTION ABORT – CLR EXAMPLE

LSN	prevLSN	TxnId	Type	Object	Before	After	UndoNext
001	nil	T_1	BEGIN	-	-	-	-
002	001	T_1	UPDATE	A	30	40	-
⋮							
011	002	T_1	ABORT	-	-	-	-
⋮							
026	011	T_1	CLR	A	40	30	001
027	026	T_1	TXN-END	-	-	-	nil

ABORT ALGORITHM

First write an **ABORT** record to log.

Then play back updates in reverse order. For each update:

- Write a **CLR** entry.
- Restore old value.

At end, write a **TXN-END** log record.

Notice: **CLRs** never need to be undone.

TODAY'S AGENDA

~~Log Sequence Numbers~~

~~Normal Commit & Abort Operations~~

Fuzzy Checkpointing

Recovery Algorithm

NON-FUZZY CHECKPOINTS

The DBMS halts everything when it takes a checkpoint to ensure a consistent snapshot:

- Halt the start of any new txns.
- Wait until all active txns finish executing.
- Flushes dirty pages on disk.

This is obviously bad...

SLIGHTLY BETTER CHECKPOINTS

Pause txns while the DBMS takes the checkpoint.

→ We don't have to wait until all txns finish before taking the checkpoint.

SLIGHTLY BETTER CHECKPOINTS

Pause txns while the DBMS takes the checkpoint.

→ We don't have to wait until all txns finish before taking the checkpoint.

SLIGHTLY BETTER CHECKPOINTS

Pause txns while the DBMS takes the checkpoint.

→ We don't have to wait until all txns finish before taking the checkpoint.

SLIGHTLY BETTER CHECKPOINTS

Pause txns while the DBMS takes the checkpoint.

→ We don't have to wait until all txns finish before taking the checkpoint.

SLIGHTLY BETTER CHECKPOINTS

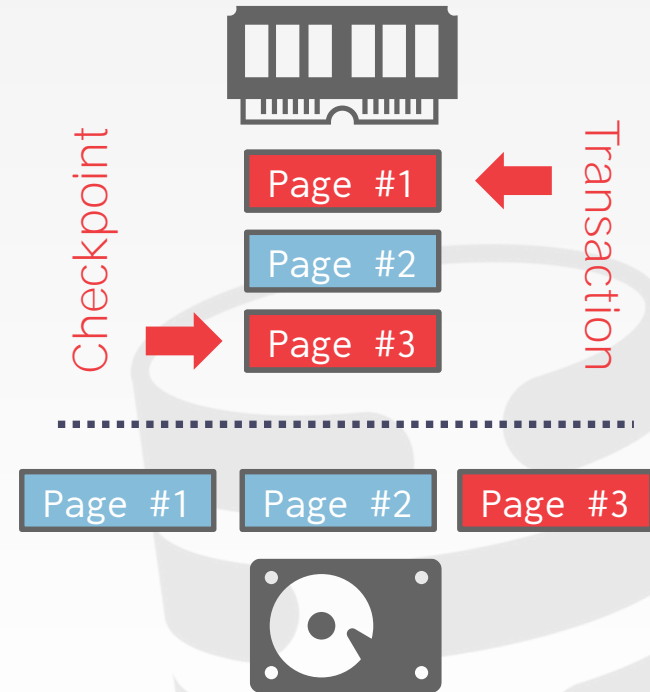

Pause txns while the DBMS takes the checkpoint.

→ We don't have to wait until all txns finish before taking the checkpoint.

We have to record internal state as of the beginning of the checkpoint.

→ **Active Transaction Table (ATT)**

→ **Dirty Page Table (DPT)**

ACTIVE TRANSACTION TABLE

One entry per currently active txn.

- **txnId**: Unique txn identifier.
- **status**: The current "mode" of the txn.
- **lastLSN**: Most recent *LSN* created by txn.

Entry removed when txn commits or aborts.

Status Codes:

- **R** → Running
- **C** → Committing
- **U** → Candidate for Undo

DIRTY PAGE TABLE

Keep track of which pages in the buffer pool contain changes from uncommitted transactions.

One entry per dirty page:

→ **recLSN**: The *LSN* of the log record that first caused the page to be dirty.

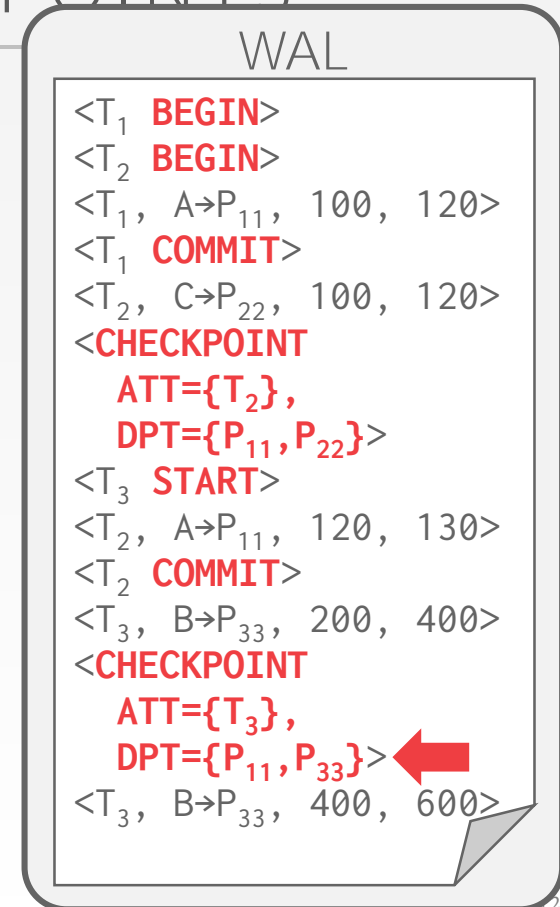

SLIGHTLY BETTER CHECKPOINTS

At the first checkpoint, T_2 is still running and there are two dirty pages (P_{11} , P_{22}).

At the second checkpoint, T_3 is active and there are two dirty pages (P_{11} , P_{33}).

This still isn't ideal because we have to stall all txns during checkpoint...

FUZZY CHECKPOINTS

A fuzzy checkpoint is where the DBMS allows other txns to continue the run.

New log records to track checkpoint boundaries:

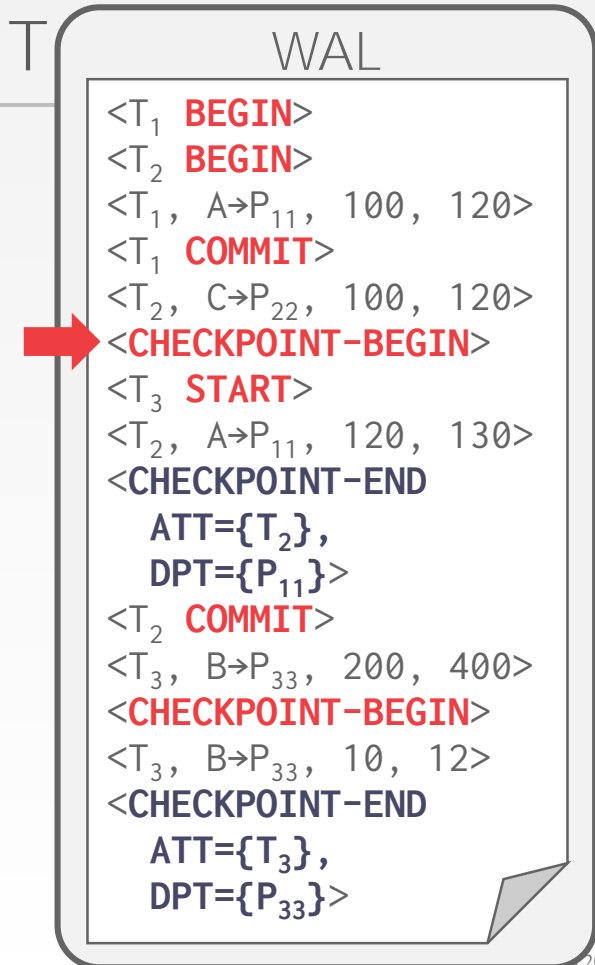

- **CHECKPOINT-BEGIN**: Indicates start of checkpoint
- **CHECKPOINT-END**: Contains **ATT** + **DPT**.

FUZZY CHECKPOINT

The *LSN* of the **CHECKPOINT-BEGIN** record is written to the database's **MasterRecord** entry on disk.

Any txn that starts after the checkpoint is excluded from the txn table listing.

FUZZY CHECKPOINT

The *LSN* of the **CHECKPOINT-BEGIN** record is written to the database's **MasterRecord** entry on disk.

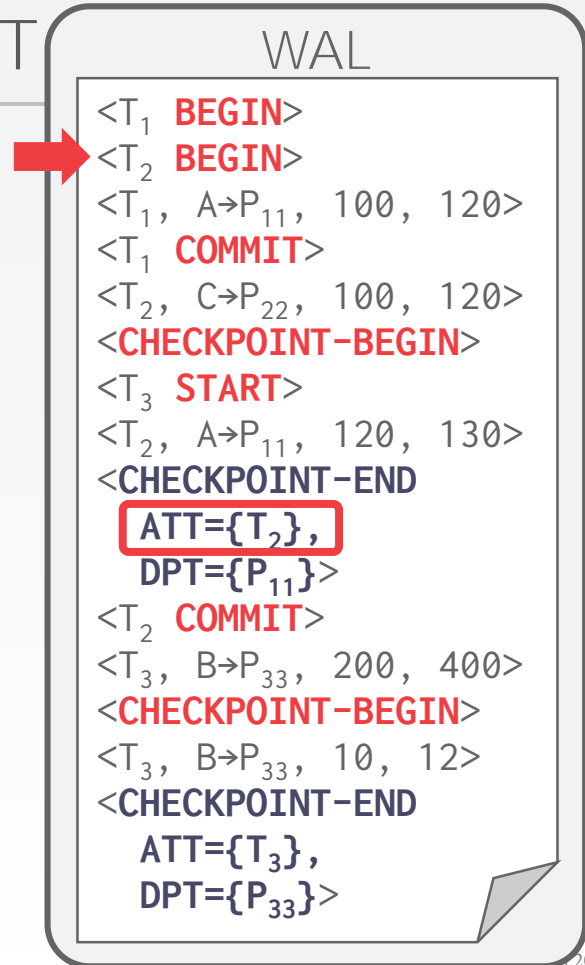

Any txn that starts after the checkpoint is excluded from the txn table listing.

FUZZY CHECKPOINT

The *LSN* of the **CHECKPOINT-BEGIN** record is written to the database's **MasterRecord** entry on disk.

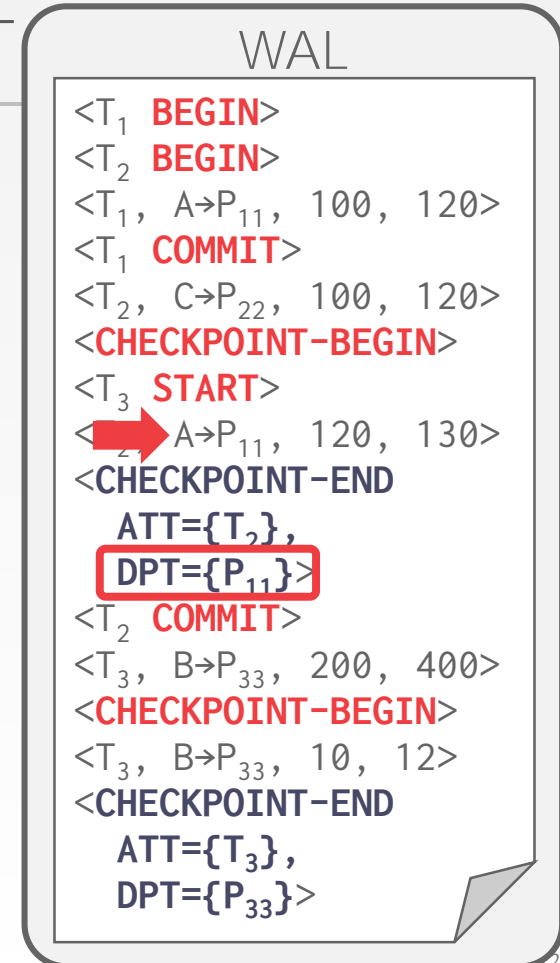

Any txn that starts after the checkpoint is excluded from the txn table listing.

FUZZY CHECKPOINT

The *LSN* of the **CHECKPOINT-BEGIN** record is written to the database's **MasterRecord** entry on disk.

Any txn that starts after the checkpoint is excluded from the txn table listing.

ARIES – RECOVERY PHASES

Phase #1 – Analysis

→ Read the WAL to identify dirty pages in the buffer pool and active txns at the time of the crash.

Phase #2 – Redo

→ Repeat all actions starting from an appropriate point in the log.

Phase #3 – Undo

→ Reverse the actions of txns that did not commit before the crash.

ARIES – OVERVIEW

Start from last **BEGIN-CHECKPOINT** found via **MasterRecord**.

Analysis: Figure out which txns committed or failed since checkpoint.

Redo: Repeat all actions.

Undo: Reverse effects of failed txns.

ANALYSIS PHASE

Scan log forward from last successful checkpoint.

If you find a **TXN-END** record, remove its txn from **ATT**.

All other records:

→ Add txn to **ATT** with status **UNDO**.

→ On commit, change txn status to **COMMIT**.

For **UPDATE** records:

→ If page **P** not in **DPT**, add **P** to **DPT**, set its **recLSN=LSN**.

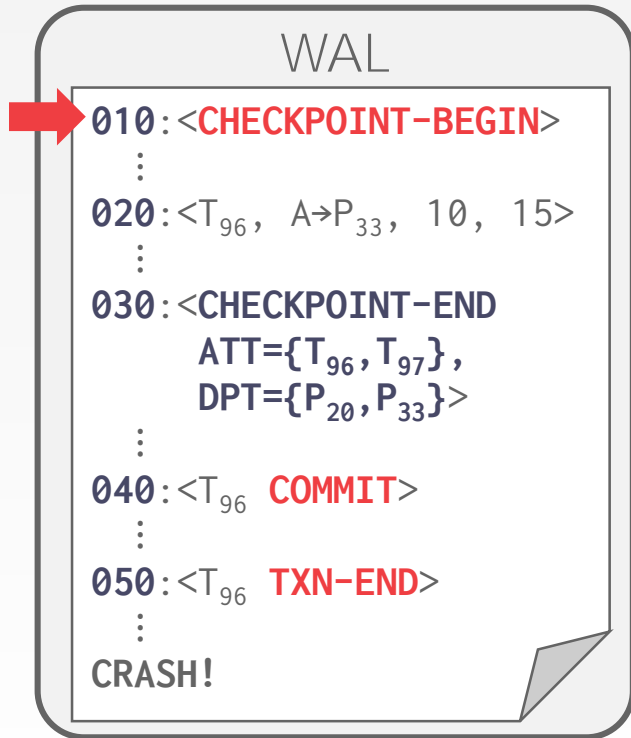

ANALYSIS PHASE

At end of the Analysis Phase:

- **ATT** tells the DBMS which txns were active at time of crash.
- **DPT** tells the DBMS which dirty pages might not have made it to disk.

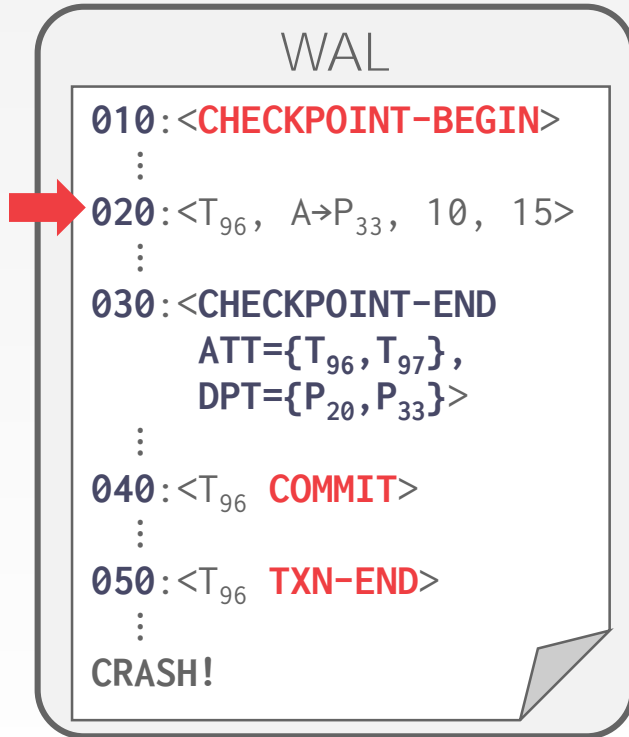

ANALYSIS PHASE EXAMPLE

LSN	ATT	DPT
010		
020		
030

010		
020	(T ₉₆ , U)	(P ₃₃ , 020)
030	(T ₉₆ , U), (T ₉₇ , U)	(P ₃₃ , 020), (P ₂₀ , 022)
040	(T ₉₆ , C), (T ₉₇ , U)	(P ₃₃ , 020), (P ₂₀ , 022)
050	(T ₉₇ , U)	(P ₃₃ , 020), (P ₂₀ , 022)

REDO PHASE

The goal is to repeat history to reconstruct state at the moment of the crash:

→ Reapply all updates (even aborted txns!) and redo **CLRs**.

There techniques that allow the DBMS to avoid unnecessary reads/writes, but we will ignore that in this lecture...

REDO PHASE

Scan forward from the log record containing smallest **recLSN** in **DPT**.

For each update log record or *CLR* with a given *LSN*, redo the action unless:

- Affected page is not in the **DPT**, or
- Affected page is in **DPT** but that record's *LSN* is greater than smallest **recLSN**, or
- Affected **pageLSN** (on disk) \geq record's *LSN*

REDO PHASE

To redo an action:

- Reapply logged action.
- Set **pageLSN** to log record's *LSN*.
- No additional logging, no forcing!

At the end of Redo Phase, write **TXN-END** log records for all txns with status **C** and remove them from the **ATT**.

UNDO PHASE

Undo all txns that were active at the time of crash and therefore will never commit.

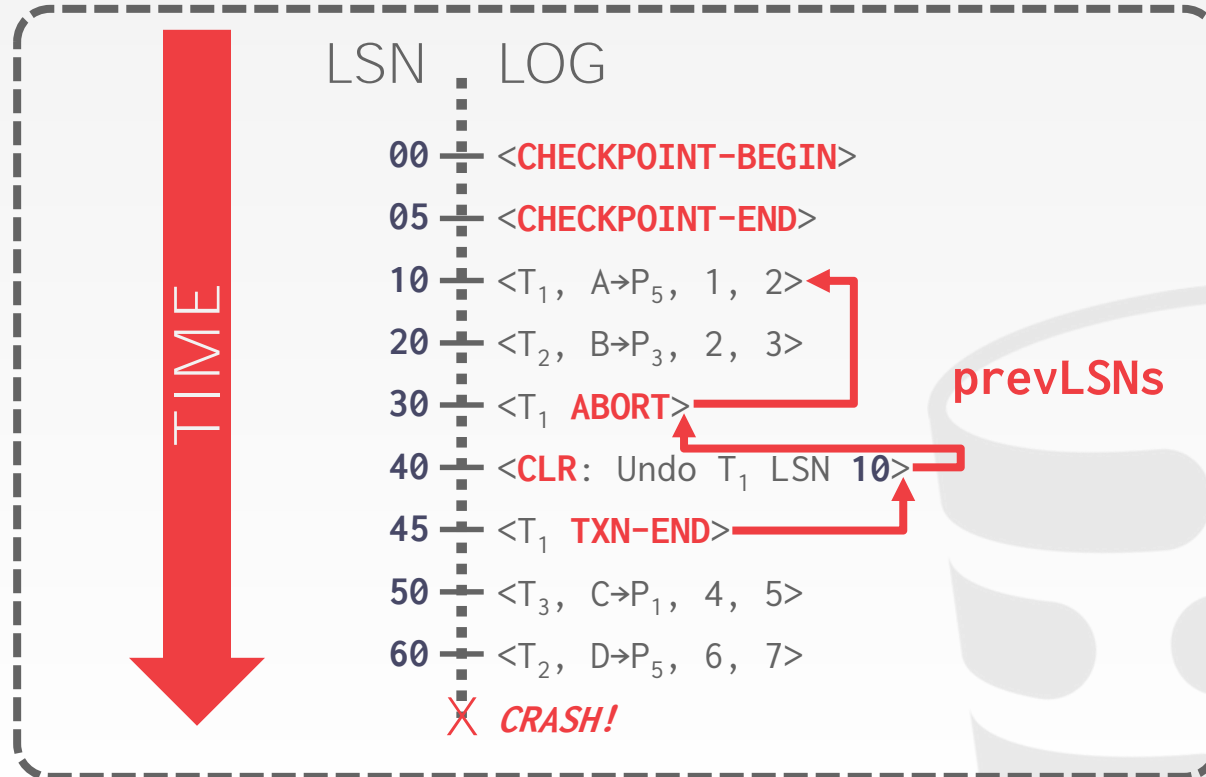

→ These are all txns with **U** status in the **ATT** after the Analysis Phase.

Process them in reverse **LSN** order using the **lastLSN** to speed up traversal.

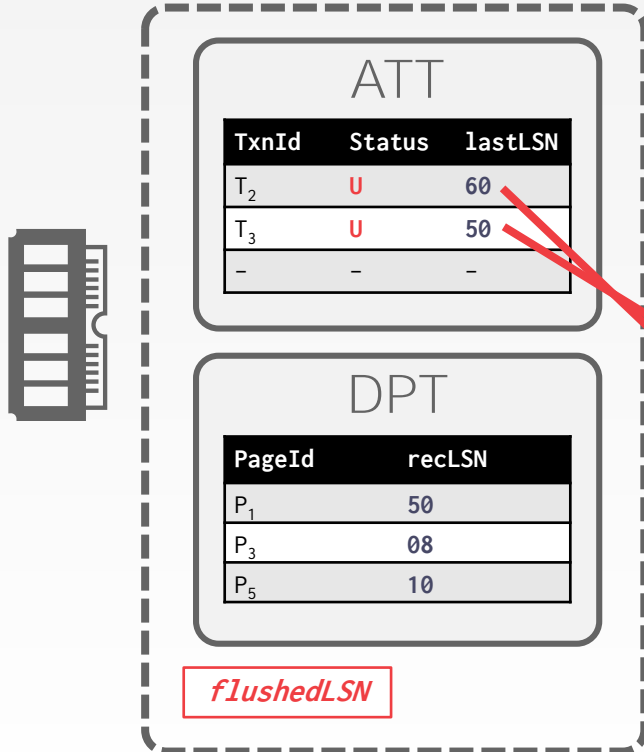

Write a **CLR** for every modification.

Flush WAL to disk!

FULL EXAMPLE

FULL EXAMPLE

ADDITIONAL CRASH ISSUES (1)

What does the DBMS do if it crashes during recovery in the Analysis Phase?

→ Nothing. Just run recovery again.

What does the DBMS do if it crashes during recovery in the Redo Phase?

→ Again nothing. Redo everything again.

ADDITIONAL CRASH ISSUES (2)

How can the DBMS improve performance during recovery in the Redo Phase?

→ Assume that it is not going to crash again and flush all changes to disk asynchronously in the background.

How can the DBMS improve performance during recovery in the Undo Phase?

→ Lazily rollback changes before new txns access pages.

→ Rewrite the application to avoid long-running txns.

CONCLUSION

Mains ideas of ARIES:

- WAL with **STEAL/NO-FORCE**
- Fuzzy Checkpoints (snapshot of dirty page ids)
- Redo everything since the earliest dirty page
- Undo txns that never commit
- Write **CLRs** when undoing, to survive failures during restarts

Log Sequence Numbers:

- **LSNs** identify log records; linked into backwards chains per transaction via **prevLSN**.
- **pageLSN** allows comparison of data page and log records.

NEXT CLASS

You now know how to build a single-node DBMS.

So now we can talk about distributed databases!
