CARNEGIE MELLON UNIVERSITY COMPUTER SCIENCE DEPARTMENT 15-445/645 – DATABASE SYSTEMS (FALL 2019) PROF. ANDY PAVLO

Homework #5 (by Zhaozhe Song) – Solutions Due: **Tuesday Dec 3, 2019 @ 11:59pm**

IMPORTANT:

- Upload this PDF with your answers to Gradescope by 11:59pm on Tuesday Dec 3, 2019.
- **Plagiarism**: Homework may be discussed with other students, but all homework is to be completed **individually**.
- You have to use this PDF for all of your answers.

For your information:

Total:	100	

Number of Days this Assignment is Late:

Number of Late Day You Have Left:

The following messages have been sent:

time	message
1	N_0 to N_1 : "Phase1:PREPARE"
2	N_0 to N_2 : "Phase1:PREPARE"
3	
4	N_0 to N_3 : "Phase1:PREPARE"
5	N_3 to N_0 : " OK "

Figure 1: Two-Phase Commit messages for transaction T

- (a) **[10 points]** Who should send a message next at time 6 in Figure 1? Select *all* the possible answers.
 - $\Box N_0$
 - $\Box N_1$
 - \blacksquare N_2
 - $\Box N_3$

 \Box It is not possible to determine

Solution: N_2 has to send a response to N_0

- (b) **[10 points]** To whom? Again, select *all* the possible answers.
 - \square N₀
 - $\Box N_1$
 - $\square N_2$
 - $\Box N_3$
 - \Box It is not possible to determine

Solution: N_2 has to send a response to N_0

- (c) [10 points] Suppose that N_0 received the "ABORT" response from N_3 at time 5 in Figure 1. What should happen under the two-phase commit protocol in this scenario?
 - \Box N₀ resends "Phase1: PREPARE" to N₃
 - \Box N₀ resends "**Phase1: PREPARE**" to all of the participant nodes
 - \blacksquare N₀ sends "ABORT" all of the participant nodes
 - \Box N₀ sends "**Phase2:COMMIT**" all of the participant nodes
 - \Box N₃ resends "**OK**" to N₀
 - \Box It is not possible to determine

Solution: The coordinator (N_0) will mark the transaction as aborted. 2PC requires that *all* participants respond with "**OK**".

- (d) **[10 points]** Suppose that N_0 successfully receives all of the "**OK**" messages from the participants from the first phase (i.e., after time 6 in Figure 1). It then sends the "**Phase2:COMMIT**" message to all of the participants at time 7 but N_2 crashes before it receives this message. What is the status of the transaction T when N_2 comes back on-line?
 - *T*'s status is *committed*
 - \Box *T*'s status is *aborted*
 - \Box It is not possible to determine

Solution: Once the coordinator (N_0) gets a "**OK**" message from *all* participants, then the transaction is considered to be committed even though a node may crash during the second phase. In this example, N_2 would have restore T when it comes back on-line.

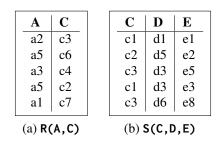

Table 1: Sample database

- (a) Consider the relations R(A,C) and S(C,D,E) shown in Table 1, where attribute S.C is a foreign key of attribute R.C.
 - i. **[10 points]** What is the output of $R \ltimes S$?
 - $\Box \{ (a2,c3,d4,e5), (a2,c3,d6,e8), (a5, c2, d3, e2) \}$
 - $\Box \{ (a2,c3,d4,e5), (a5, c2, d3, e2) \}$
 - $\Box \{ (c2,b3,a5), (c2,d3,e2), (c3,d4,e5), (c3,d6,e8) \}$
 - $\Box \left\{ (a2), (a5) \right\}$
 - { (a5,c2), (a2,c3) }
 - $\Box \{ (a5,c2), (a2,c3), (a5,c3) \}$
 - \Box None of the above

ii. **[10 points]** What is the output of $S \ltimes R$?

- { (c3,d6,e8), (c3,d3,e5), (c2,d5,e2) }
- $\Box \{ (c2,d3,e2), (a1,b2,c3), (c3,d6,e8), (c3,d4,e5), (a5,b3,c2) \}$
- $\Box \{ (c2,d5,e2), (c3,d3,e5) \}$
- $\Box \{ (c2,d3,e2), (c1,d4,e1), (c3,d6,e8), (c1,d2,e3), (c3,d4,e5) \}$
- $\Box \left\{ (d3,e2), (d6,e8) \right\}$
- $\Box \{ (c2,d5,e2), (c3,d6,e8) \}$
- \Box None of the above

(b) **[5 points]** In general, is the semijoin operation symmetric for every possible database? That is, is the following equation always true for any possible relations *R*1 and *R*2?

$$R1 \ltimes R2 = ?R2 \ltimes R1 \tag{1}$$

□ Yes

No

 \Box It is not possible to determine

Solution: Consider a database where $R1(A,B) = \{ (a1,b1) \}, R2(A,C) = \{ (a1,c1) \}$ Then, $(R1 \ltimes R2 = R1) \neq (R2 \ltimes R1 = R2)$ The database has a single table foo(<u>id</u>, val) with the following tuples:

id	val
1	ууу
2	XXX

Table 2: foo(id,val)

For each questions listed below, assume that the following transactions shown in Figure 2 are executing in the DBMS: (1) Transaction #1 on NODE A and (2) Transaction #2 on NODE B. You can assume that the timestamps for each operation is the real physical time of when it was invoked at the DBMS and that the clocks on both nodes are perfectly synchronized (again, this is not a realistic assumption).

time	operation	time	operation
	BEGIN;	2	BEGIN READ ONLY;
2	UPDATE foo SET val = 'aaa';	3	SELECT val FROM foo WHERE id = 1;
3	UPDATE foo SET val = 'bbb' WHERE id = 2;	(4)	SELECT val FROM foo WHERE id = 2;
(4)	UPDATE foo SET val = 'ccc' WHERE id = 1;	(5)	SELECT val FROM foo WHERE id = 2;
(5)	COMMIT;	6	COMMIT;

(a) Transaction #1 - NODE A

(b) Transaction #2 - NODE B

Figure 2: Transactions executing in the DBMS.

- (a) Assume that the DBMS is using *asynchronous* replication with *continuous* log streaming (i.e., the master node sends log records to the replica in the background after the transaction executes them). Suppose that NODE A crashes at timestamp (5) <u>before</u> it executes the COMMIT operation.
 - i. **[10 points]** If Transaction #2 is running under SNAPSHOT ISOLATION, what is the return result of the val attribute for its SELECT query at timestamp ④? Select all that are possible.
 - 🗆 aaa
 - \Box bbb
 - \Box ccc
 - XXX
 - \Box None of the above

Solution: SNAPSHOT ISOLATION means that the transaction will only see the versions that were committed before it started. That means at ④, Transaction #1 has not committed yet so therefore Transaction #2 cannot see any of its versions.

- ii. **[10 points]** If Transaction #2 is running under the READ UNCOMMITTED isolation level, what is the return result of the val attribute for its SELECT query at timestamp ④? Select all that are possible.
 - 🔳 aaa

 - bbb
 - \Box ccc
 - 🗆 ууу
 - \Box None of the above

Solution: READ UNCOMMITTED means that it will read any version of the tuple that exists in the database. But what version of tuple 1 that the transaction will read depends on whether the master node shipped the log record over before the query is executed. Since we are doing continuous log shipping, we have no idea. So it could read the version of the tuple that existed *before* Transaction #1 started (i.e., "xxx") or after Transaction #1 executed the UPDATE query at (2) (i.e., "aaa"), or after Transaction #1 executed the UPDATE query at (3) (i.e., "bbb").

(b) **[15 points]** Assume that the DBMS is using *synchronous* replication with *continuous* log streaming. Suppose that both NODE A and NODE B crash at exactly the same time at timestamp ⁽⁶⁾ <u>after</u> executing Transaction #1's COMMIT operation. You can assume that the application was notified that the Transaction #1 was committed successfully.

After the crash, you find that NODE A had a major hardware failure and cannot boot. NODE B is able to recover and is elected the new master.

What are the values of the tuples in the database when the system comes back online? Select all that are possible.

- $\Box \{ (1,aaa), (2,bbb) \}$
- \blacksquare { (1,ccc), (2,bbb) }
- $\Box \{ (1, xxx), (2, xxx) \}$
- $\Box \{ (1, yyy), (2, bbb) \}$
- $\Box \left\{ (1, yyy), (2, xxx) \right\}$
- $\Box \{ (1, yyy), (2, zzz) \}$
- \Box None of the above

Solution: Synchronous means that the replica had fully applied the changes before acknowledging the master. Then the master sent the notification to the client that the txn committed. It is guaranteed that updates were both durable on disk on the master and the replica. The fact that we are doing continuous log shipping doesn't matter here because the transaction's changes are either committed or aborted. There cannot be any partial updates to the database.
