Timestamp Ordering
Concurrent Control
CONCURRENCY CONTROL APPROACHES

Two-Phase Locking (2PL)
→ Determine serializability order of conflicting operations at runtime while txns execute.

Timestamp Ordering (T/O)
→ Determine serializability order of txns before they execute.

Pessimistic

Optimistic
T/O CONCURRENCY CONTROL

Use timestamps to determine the serializability order of txns.

If $\text{TS}(T_i) < \text{TS}(T_j)$, then the DBMS must ensure that the execution schedule is equivalent to a serial schedule where $T_i$ appears before $T_j$. 
Each txn $T_i$ is assigned a unique fixed timestamp that is monotonically increasing.

→ Let $TS(T_i)$ be the timestamp allocated to txn $T_i$.
→ Different schemes assign timestamps at different times during the txn.

Multiple implementation strategies:
→ System Clock.
→ Logical Counter.
→ Hybrid.
TODAY'S AGENDA

Basic Timestamp Ordering Protocol
Optimistic Concurrency Control
Partition-based Timestamp Ordering
Isolation Levels
BASIC T/O

Txns read and write objects without locks.

Every object $X$ is tagged with timestamp of the last txn that successfully did read/write:

$\rightarrow \text{W-}TS(X)$ – Write timestamp on $X$
$\rightarrow \text{R-}TS(X)$ – Read timestamp on $X$

Check timestamps for every operation:

$\rightarrow$ If txn tries to access an object "from the future", it aborts and restarts.
BASIC T/O – READS

If $\text{TS}(T_i) < \text{W-TS}(X)$, this violates timestamp order of $T_i$ with regard to the writer of $X$.
→ Abort $T_i$ and restart it with a newer TS.
Else:
→ Allow $T_i$ to read $X$.
→ Update $\text{R-TS}(X)$ to $\max(\text{R-TS}(X), \text{TS}(T_i))$
→ Have to make a local copy of $X$ to ensure repeatable reads for $T_i$. 
BASIC T/O – WRITES

If $\text{TS}(T_i) < R - \text{TS}(X)$ or $\text{TS}(T_i) < W - \text{TS}(X)$
→ Abort and restart $T_i$.

Else:
→ Allow $T_i$ to write $X$ and update $W - \text{TS}(X)$
→ Also have to make a local copy of $X$ to ensure repeatable reads for $T_i$.

- We do not update $W$-TS(A)
- Ignore the write and allow $T_1$ to commit.
BASIC T/O

Generates a schedule that is conflict serializable if you do **not** use the Thomas Write Rule.

→ No deadlocks because no txn ever waits.
→ Possibility of starvation for long txns if short txns keep causing conflicts.

Permits schedules that are not **recoverable**.
RECOVERABLE SCHEDULES

A schedule is recoverable if txns commit only after all txns whose changes they read, commit.

Otherwise, the DBMS cannot guarantee that txns read data that will be restored after recovering from a crash.
RECOVERABLE SCHEDULES

Schedule

T₁

BEGIN
W(A)
:

T₂

BEGIN
R(A)
W(B)
COMMIT

T₂ is allowed to read the writes of T₁.
### Recoverable Schedules

**Schedule**

- **T₁**
  - BEGIN
  - W(A)
  - :
  - ABORT

- **T₂**
  - BEGIN
  - R(A)
  - W(B)
  - COMMIT

**T₂ is allowed to read the writes of T₁.**

**T₁ aborts after T₂ has committed.**
**RECOVERABLE SCHEDULES**

Schedule

\[ T_1 \]

BEGIN
W(A)

\[ T_2 \]

BEGIN
R(A)
W(B)
COMMIT

\[ T_2 \] is allowed to read the writes of \( T_1 \).

\[ T_1 \] aborts after \( T_2 \) has committed.

This is not recoverable because we cannot restart \( T_1 \).
BASIC T/O – PERFORMANCE ISSUES

High overhead from copying data to txn's workspace and from updating timestamps.

Long running txns can get starved.
→ The likelihood that a txn will read something from a newer txn increases.
OBSERVATION

If you assume that conflicts between txns are rare and that most txns are short-lived, then forcing txns to wait to acquire locks adds a lot of overhead.

A better approach is to optimize for the no-conflict case.
OPTIMISTIC CONCURRENcy CONTROL

The DBMS creates a private workspace for each txn.
→ Any object read is copied into workspace.
→ Modifications are applied to workspace.

When a txn commits, the DBMS compares workspace write set to see whether it conflicts with other txns.

If there are no conflicts, the write set is installed into the "global" database.
#1 – Read Phase:
→ Track the read/write sets of txns and store their writes in a private workspace.

#2 – Validation Phase:
→ When a txn commits, check whether it conflicts with other txns.

#3 – Write Phase:
→ If validation succeeds, apply private changes to database. Otherwise abort and restart the txn.

OCC – VALIDATION PHASE

The DBMS needs to guarantee only serializable schedules are permitted.

\( T_i \) checks other txns for RW and WW conflicts and makes sure that all conflicts go one way (from older txns to younger txns).
OCC – SERIAL VALIDATION

Maintain global view of all active txns.

Record read set and write set while txns are running and write into private workspace.

Execute **Validation** and **Write** phase inside a protected critical section.
OCC – READ PHASE

Track the read/write sets of txns and store their writes in a private workspace.

The DBMS copies every tuple that the txn accesses from the shared database to its workspace ensure repeatable reads.
OCC – VALIDATION PHASE

Each txn's timestamp is assigned at the beginning of the validation phase.

Check the timestamp ordering of the committing txn with all other running txns.

If $\text{TS}(T_i) < \text{TS}(T_j)$, then one of the following three conditions must hold...
OCC – VALIDATION PHASE

When the txn invokes **COMMIT**, the DBMS checks if it conflicts with other txns.

Two methods for this phase:
→ Backward Validation
→ Forward Validation
OCC – BACKWARD VALIDATION

Check whether the committing txn intersects its read/write sets with those of any txns that have already committed.
OCC – BACKWARD VALIDATION

Check whether the committing txn intersects its read/write sets with those of any txns that have already committed.
OCC – BACKWARD VALIDATION

Check whether the committing txn intersects its read/write sets with those of any txns that have already committed.
OCC – FORWARD VALIDATION

Check whether the committing txn intersects its read/write sets with any active txns that have **not** yet committed.

Check whether the committing txn intersects its read/write sets with any active txns that have not yet committed.

OCC – OBSERVATIONS

OCC works well when the # of conflicts is low:
→ All txns are read-only (ideal).
→ Txns access disjoint subsets of data.

If the database is large and the workload is not skewed, then there is a low probability of conflict, so again locking is wasteful.
OCC – PERFORMANCE ISSUES

High overhead for copying data locally.

Validation/Write phase bottlenecks.

Aborts are more wasteful than in 2PL because they only occur after a txn has already executed.
OBSERVATION

When a txn commits, all previous T/O schemes check to see whether there is a conflict with concurrent txns.
→ This requires latches.

If you have a lot of concurrent txns, then this is slow even if the conflict rate is low.
PARTITION-BASED T/O

Split the database up in disjoint subsets called *horizontal partitions* (aka shards).

Use timestamps to order txns for serial execution at each partition.  
→ Only check for conflicts between txns that are running in the same partition.
CREATE TABLE customer (  
c_id INT PRIMARY KEY,
 c_email VARCHAR UNIQUE,
);

CREATE TABLE orders (  
o_id INT PRIMARY KEY,
o_c_id INT REFERENCES  
	customer (c_id),
);

CREATE TABLE oitems (  
oi_id INT PRIMARY KEY,
oi_o_id INT REFERENCES  
	orders (o_id),
oi_c_id INT REFERENCES  
	orders (o_c_id),
);
CREATE TABLE customer (

);  
CREATE TABLE orders (

);  
CREATE TABLE oitems (

oi_o_id INT REFERENCES \`orders\` (o_id),  
oi_c_id INT REFERENCES \`orders\` (o_c_id),  
);

PARTITION-BASED T/O

Txns are assigned timestamps based on when they arrive at the DBMS.

Partitions are protected by a single lock:
→ Each txn is queued at the partitions it needs.
→ The txn acquires a partition’s lock if it has the lowest timestamp in that partition’s queue.
→ The txn starts when it has all of the locks for all the partitions that it will read/write.
PARTITION-BASED T/O – READS

Txns can read anything that they want at the partitions that they have locked.

If a txn tries to access a partition that it does not have the lock, it is aborted + restarted.
PARTITION-BASED T/O – WRITES

All updates occur in place.
→ Maintain a separate in-memory buffer to undo changes if the txn aborts.

If a txn tries to write to a partition that it does not have the lock, it is aborted + restarted.

PARTITIONED T/O – PERFORMANCE ISSUES

Partition-based T/O protocol is fast if:
→ The DBMS knows what partitions the txn needs before it starts.
→ Most (if not all) txns only need to access a single partition.

Multi-partition txns causes partitions to be idle while txn executes.
Recall that so far we have only dealing with transactions that read and update data.

But now if we have insertions, updates, and deletions, we have new problems...
THE PHANTOM PROBLEM

Schedule

BEGIN
SELECT MAX(age)
FROM people
WHERE status='lit'
BEGIN
SELECT MAX(age)
FROM people
WHERE status='lit'
BEGIN
INSERT INTO people
(age=96, status='lit')
BEGIN
SELECT MAX(age)
FROM people
WHERE status='lit'
COMMIT
COMMIT
COMMIT

CREATE TABLE people (id SERIAL, name VARCHAR, age INT, status VARCHAR);

TIME
How did this happen?
→ Because $T_1$ locked only existing records and not ones under way!

Conflict serializability on reads and writes of individual items guarantees serializability only if the set of objects is fixed.
PREDICATE LOCKING

Lock records that satisfy a logical predicate:
→ Example: status='lit'

In general, predicate locking has a lot of locking overhead.

Index locking is a special case of predicate locking that is potentially more efficient.
INDEX LOCKING

If there is a dense index on the status field then the txn can lock index page containing the data with **status='lit'**.

If there are no records with **status='lit'**, the txn must lock the index page where such a data entry would be, if it existed.
If there is no suitable index, then the txn must obtain:

→ A lock on every page in the table to prevent a record’s `status='lit'` from being changed to `lit`.
→ The lock for the table itself to prevent records with `status='lit'` from being added or deleted.
REPEATING SCANS

An alternative is to just re-execute every scan again when the txn commits and check whether it gets the same result.

→ Have to retain the scan set for every range query in a txn.
→ Andy doesn't know of any commercial system that does this (only just Silo?).
WEAKER LEVELS OF ISOLATION

Serializability is useful because it allows programmers to ignore concurrency issues. But enforcing it may allow too little concurrency and limit performance. We may want to use a weaker level of consistency to improve scalability.
ISOLATION LEVELS

Controls the extent that a txn is exposed to the actions of other concurrent txns.

Provides for greater concurrency at the cost of exposing txns to uncommitted changes:
→ Dirty Reads
→ Unrepeatable Reads
→ Phantom Reads
ISOLATION LEVELS

**SERIALIZABLE**: No phantoms, all reads repeatable, no dirty reads.

**REPEATABLE READS**: Phantoms may happen.

**READ COMMITTED**: Phantoms and unrepeatable reads may happen.

**READ UNCOMMITTED**: All of them may happen.

</tr>
</tbody>
</table>
ISOLATION LEVELS

**SERIALIZABLE**: Obtain all locks first; plus index locks, plus strict 2PL.

**REPEATABLE READS**: Same as above, but no index locks.

**READ COMMITTED**: Same as above, but S locks are released immediately.

**READ UNCOMMITTED**: Same as above, but allows dirty reads (no S locks).
SQL-92 ISOLATION LEVELS

You set a txn's isolation level before you execute any queries in that txn.

Not all DBMS support all isolation levels in all execution scenarios → Replicated Environments

The default depends on implementation...

SET TRANSACTION ISOLATION LEVEL <isolation-level>;

BEGIN TRANSACTION ISOLATION LEVEL <isolation-level>;

SQL-92 ACCESS MODES

You can provide hints to the DBMS about whether a txn will modify the database during its lifetime.

Only two possible modes:
→ **READ WRITE** (Default)
→ **READ ONLY**

Not all DBMSs will optimize execution if you set a txn to in **READ ONLY** mode.

```sql
SET TRANSACTION <access-mode>;
BEGIN TRANSACTION <access-mode>;
```
CONCLUSION

Every concurrency control can be broken down into the basic concepts that I've described in the last two lectures.

I'm not showing benchmark results because I don't want you to get the wrong idea.
