LAST CLASS

Conflict Serializable

→ Verify using either the "swapping" method or dependency graphs.
→ Any DBMS that says that they support "serializable" isolation does this.

View Serializable

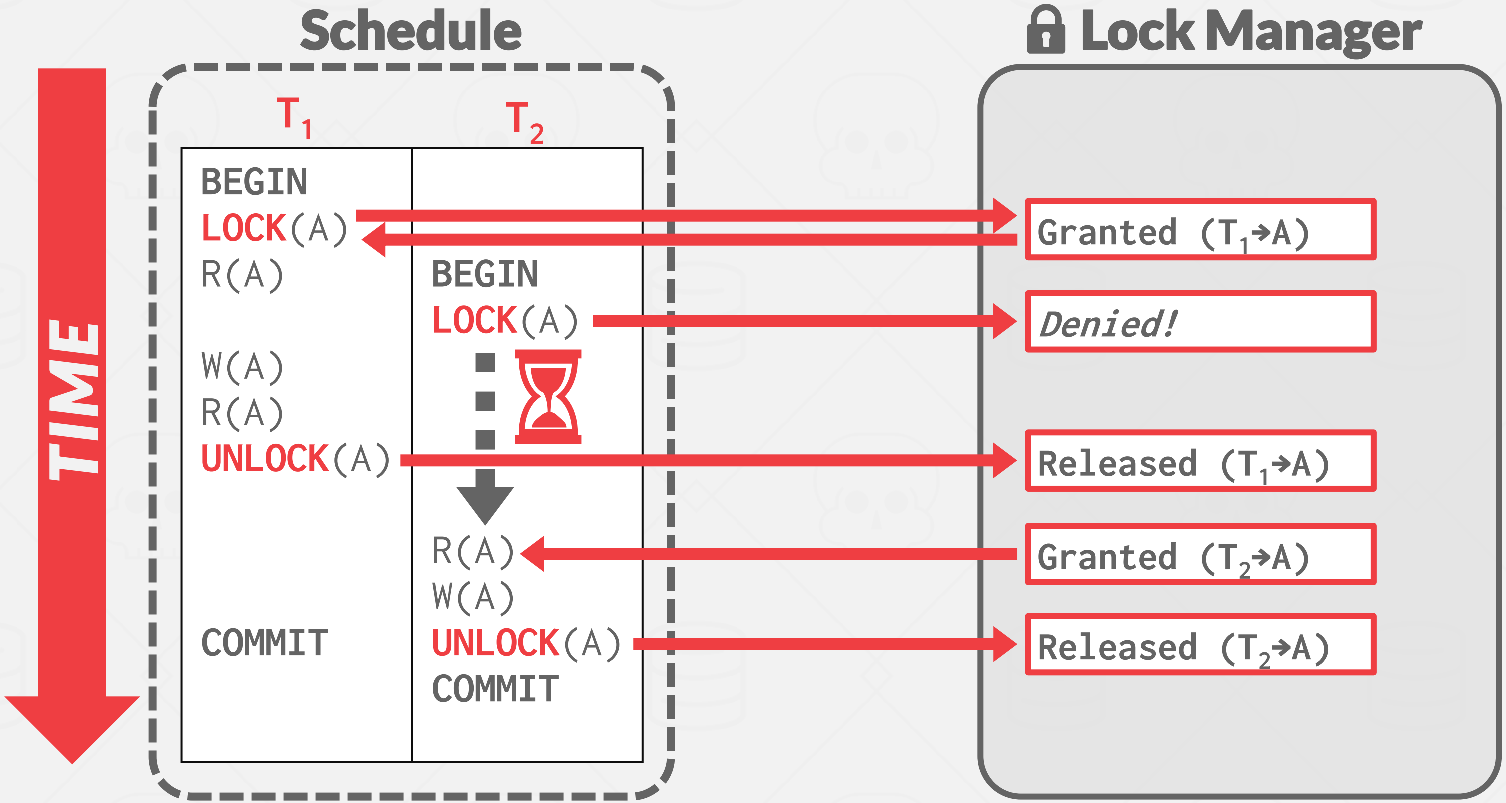
→ No efficient way to verify.
→ Andy doesn't know of any DBMS that supports this.

OBSERVATION

We need a way to guarantee that all execution schedules are correct (i.e., serializable) without knowing the entire schedule ahead of time.

Solution: Use **locks** to protect database objects.

EXECUTING WITH LOCKS



TODAY'S AGENDA

Lock Types
Two-Phase Locking
Deadlock Detection + Prevention
Hierarchical Locking

LOCKS VS. LATCHES

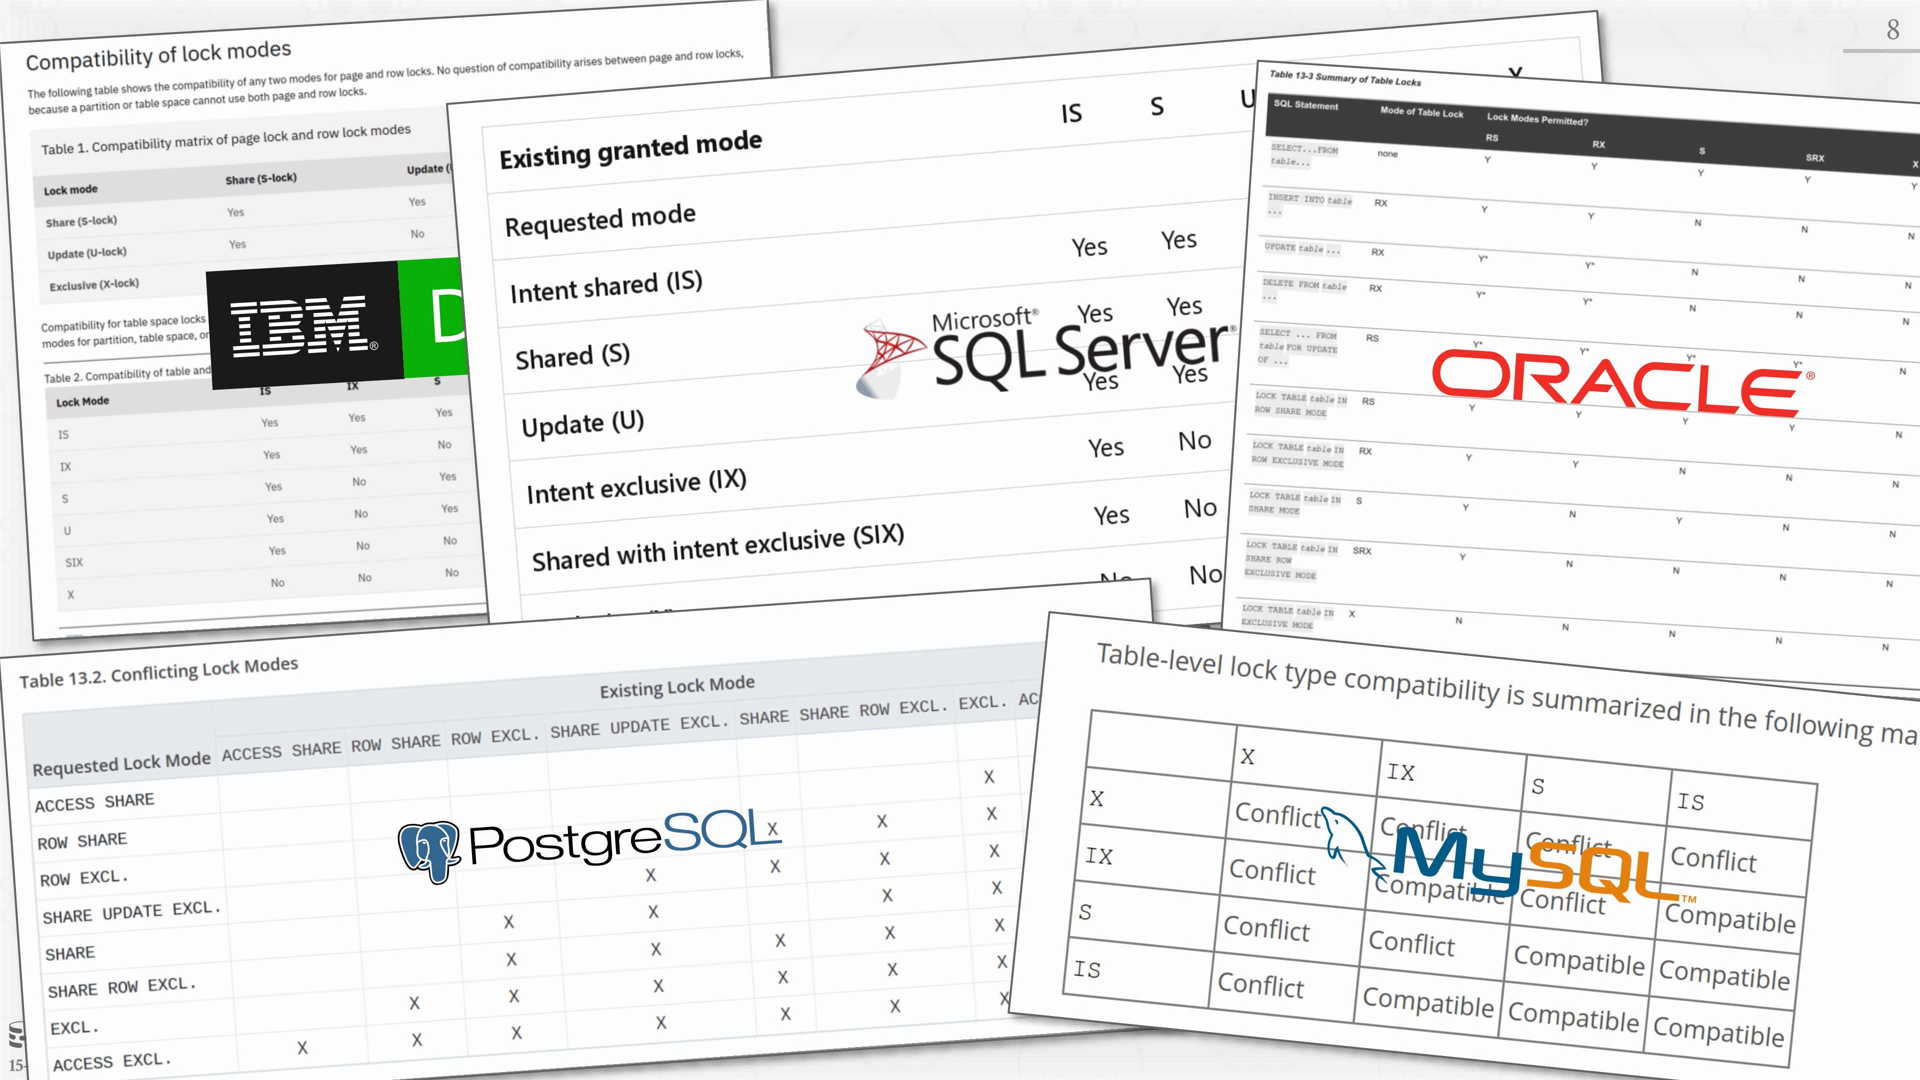
BASIC LOCK TYPES

S-LOCK: Shared locks for reads.

X-LOCK: Exclusive locks for writes.

Compatibility Matrix

	Shared	Exclusive
Shared	✓	X
Exclusive	X	X



Compatibility of lock modes
The following table shows the compatibility of any two modes for page and row locks. No question of compatibility arises between page and row locks, because a partition or table space cannot use both page and row locks.
Table 1. Compatibility matrix of page lock and row lock modes

MySQL

EXECUTING WITH LOCKS

Transactions request locks (or upgrades).

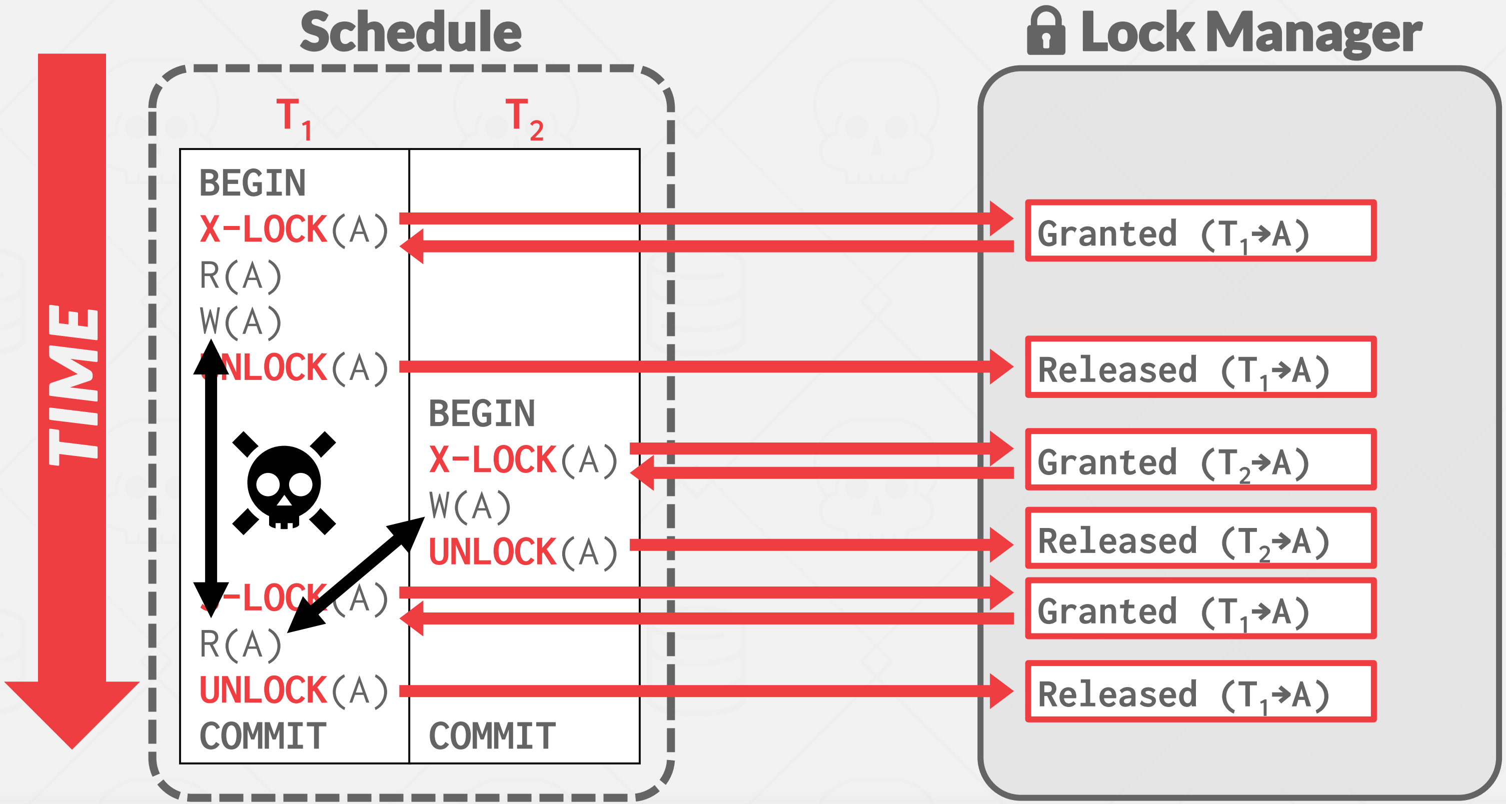
Lock manager grants or blocks requests.

Transactions release locks.

Lock manager updates its internal lock-table.

→ It keeps track of what transactions hold what locks and what transactions are waiting to acquire any locks.

EXECUTING WITH LOCKS



CONCURRENCY CONTROL PROTOCOL

Two-phase locking (2PL) is a concurrency control protocol that determines whether a txn can access an object in the database at runtime.

The protocol does not need to know all the queries that a txn will execute ahead of time.

TWO-PHASE LOCKING

Phase #1: Growing

→ Each txn requests the locks that it needs from the DBMS's lock manager.

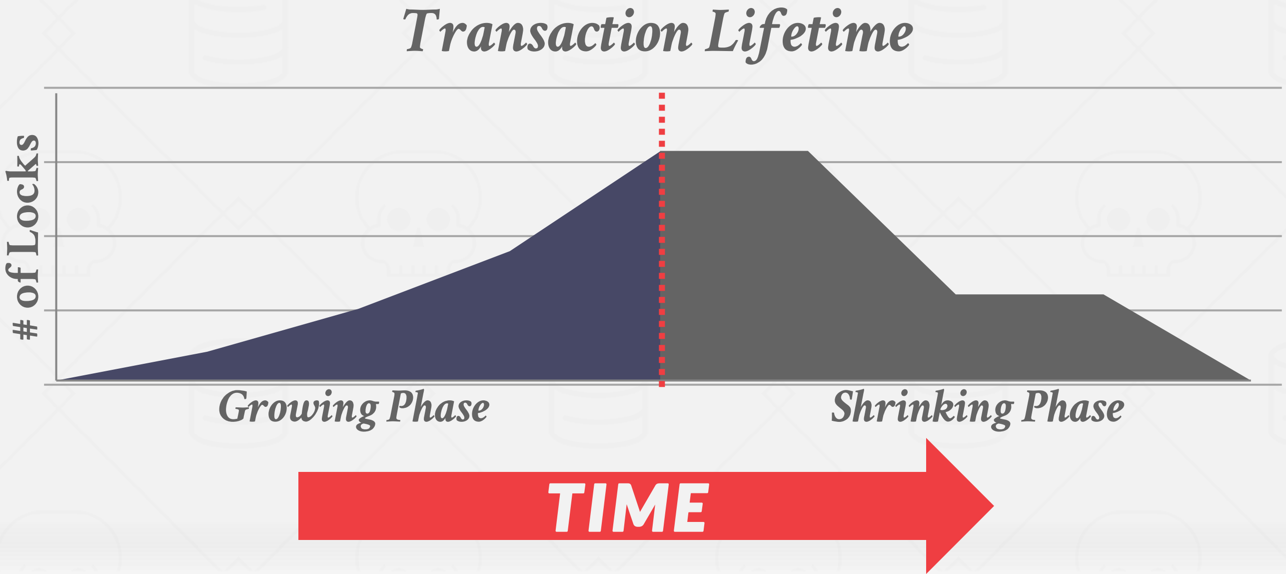
→ The lock manager grants/denies lock requests.

Phase #2: Shrinking

→ The txn is allowed to only release/downgrade locks that it previously acquired. It cannot acquire new locks.

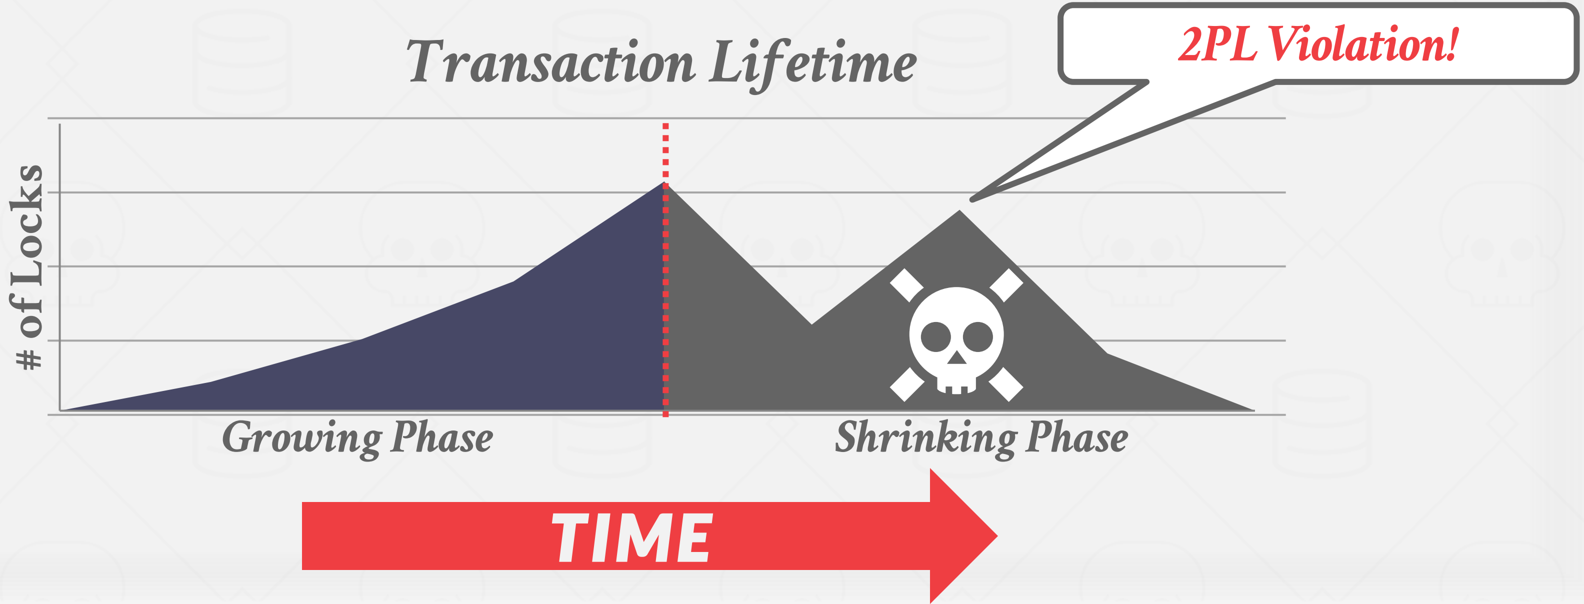
TWO-PHASE LOCKING

The txn is not allowed to acquire/upgrade locks after the growing phase finishes.

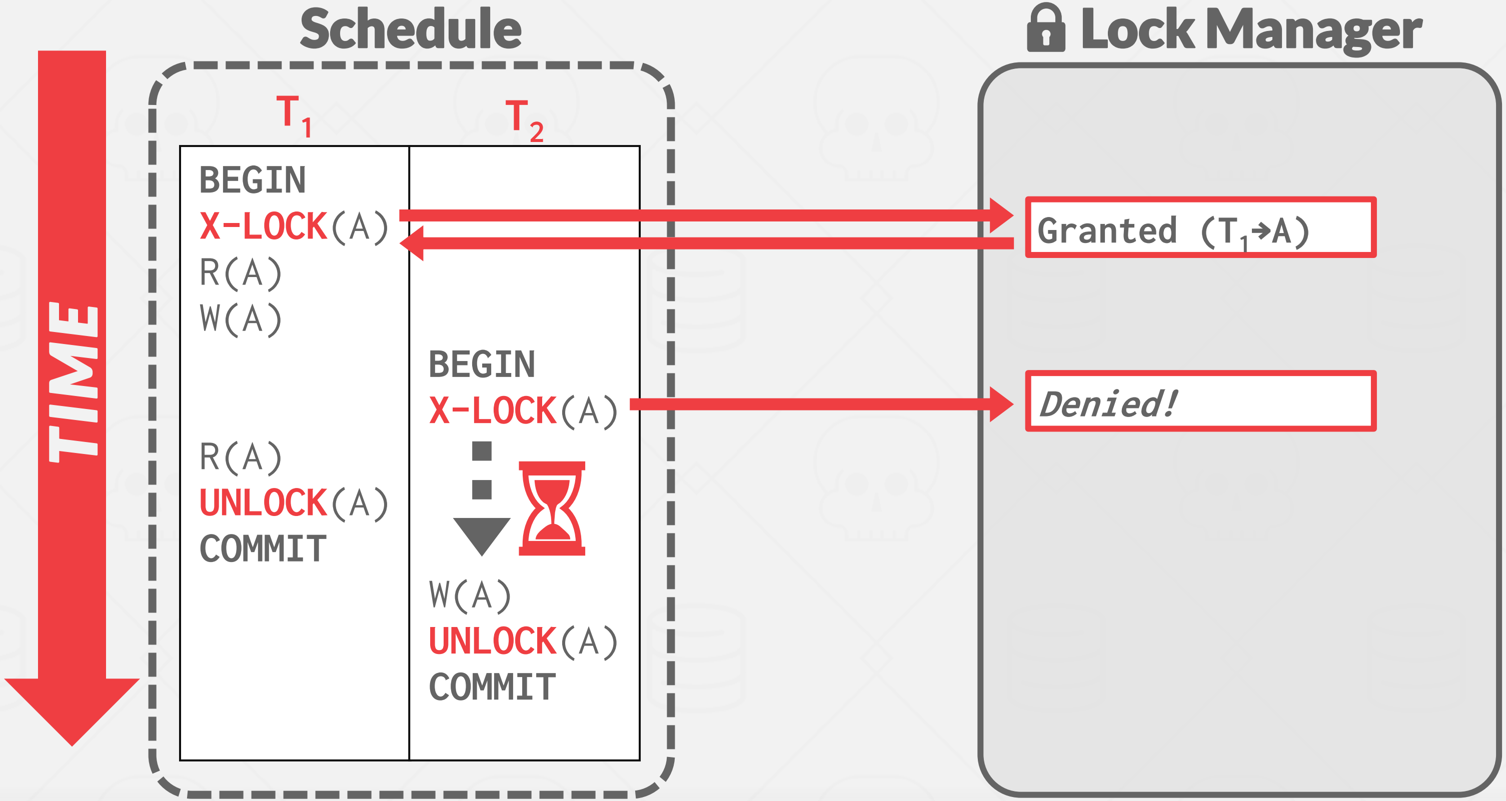


TWO-PHASE LOCKING

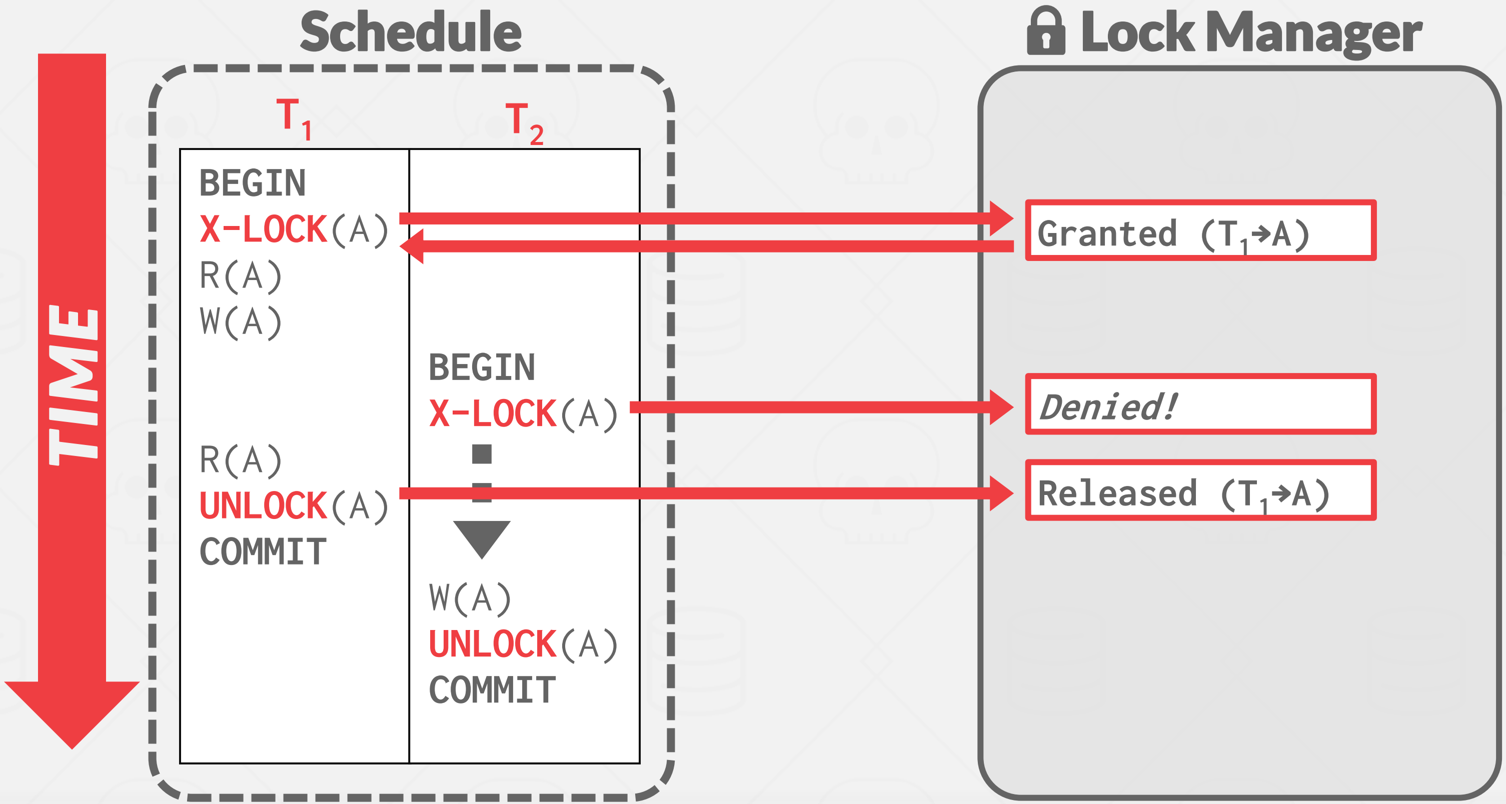
The txn is not allowed to acquire/upgrade locks after the growing phase finishes.



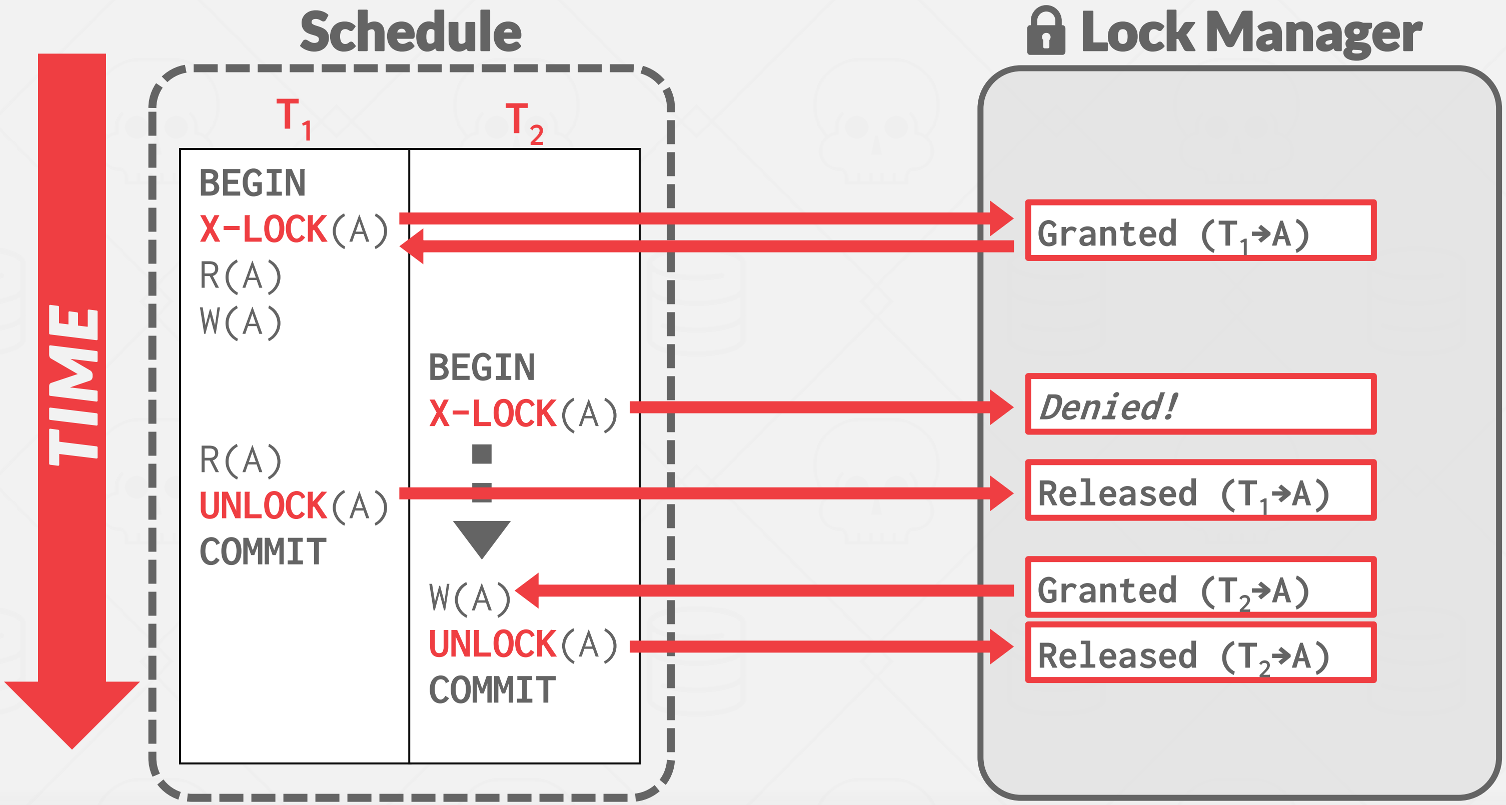
EXECUTING WITH 2PL



EXECUTING WITH 2PL



EXECUTING WITH 2PL



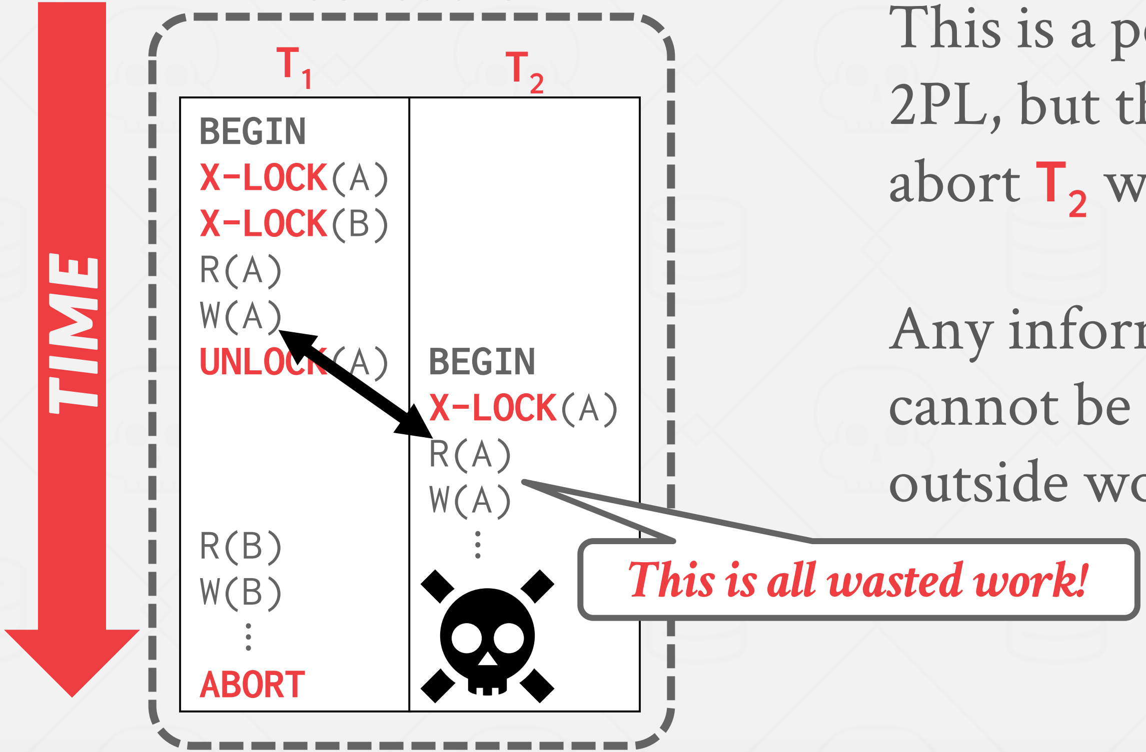
TWO-PHASE LOCKING

2PL on its own is sufficient to guarantee conflict serializability because it generates schedules whose precedence graph is acyclic.

But it is subject to **cascading aborts**.

2PL – CASCADING ABORTS

Schedule



This is a permissible schedule in 2PL, but the DBMS has to also abort T_2 when T_1 aborts.

Any information about T_1 cannot be "leaked" to the outside world.

2PL OBSERVATIONS

There are potential schedules that are serializable but would not be allowed by 2PL because locking limits concurrency.

→ Most DBMSs prefer correctness before performance.

May still have "dirty reads".

→ Solution: **Strong Strict 2PL (aka Rigorous 2PL)**

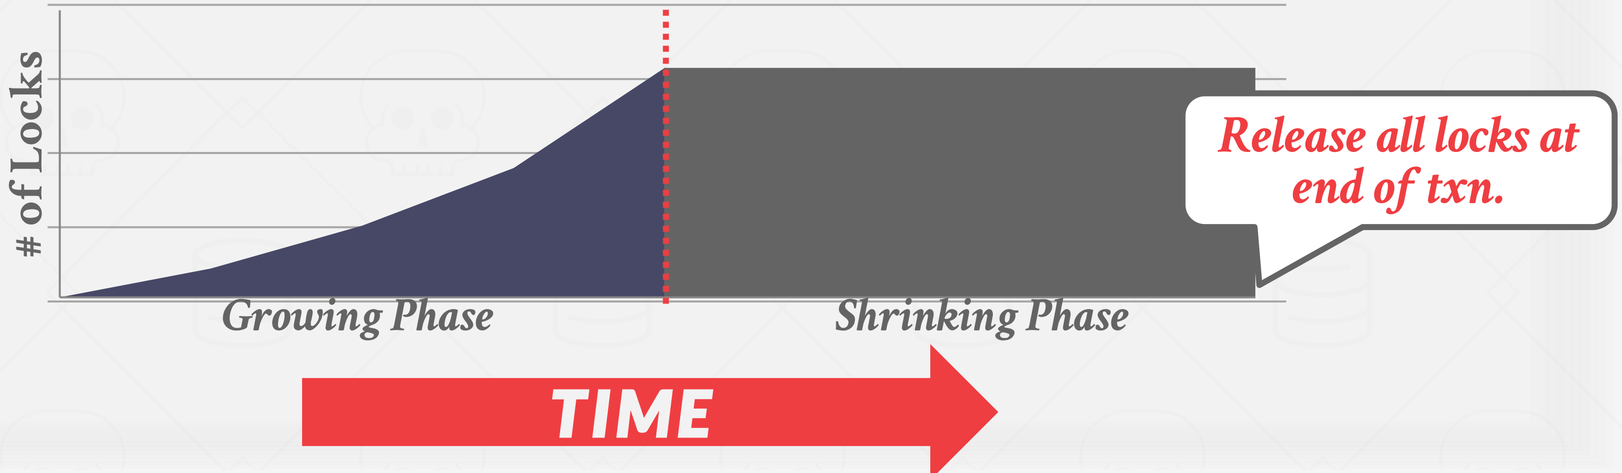
May lead to deadlocks.

→ Solution: **Detection** or **Prevention**

STRONG STRICT TWO-PHASE LOCKING

The txn is only allowed to release locks after it has ended (i.e., committed or aborted).

Allows only conflict serializable schedules, but it is often stronger than needed for some apps.



STRONG STRICT TWO-PHASE LOCKING

A schedule is **strict** if a value written by a txn is not read or overwritten by other txns until that txn finishes.

Advantages:

→ Does not incur cascading aborts.

→ Aborted txns can be undone by just restoring original values of modified tuples.

EXAMPLES

T_1 – Move $100 from Andy's account (**A**) to his bookie's account (**B**).

T_2 – Compute the total amount in all accounts and return it to the application.

T_1

```
BEGIN
A=A-100
B=B+100
COMMIT
```

T_2

```
BEGIN
ECHO A+B
COMMIT
```

NON-2PL EXAMPLE

Schedule

TIME

T_1	T_2
BEGIN	BEGIN
X-LOCK(A)

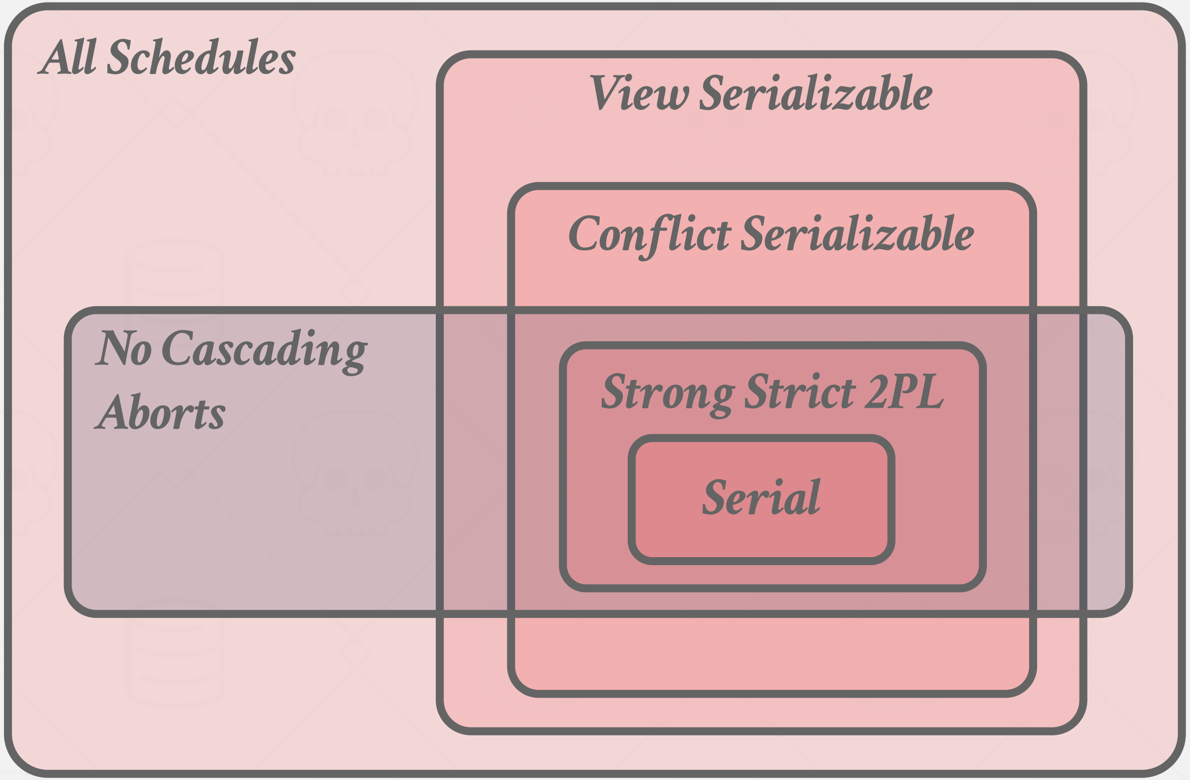
UNIVERSE OF SCHEDULES



2PL OBSERVATIONS

There are potential schedules that are serializable but would not be allowed by 2PL because locking limits concurrency.

→ Most DBMSs prefer correctness before performance.

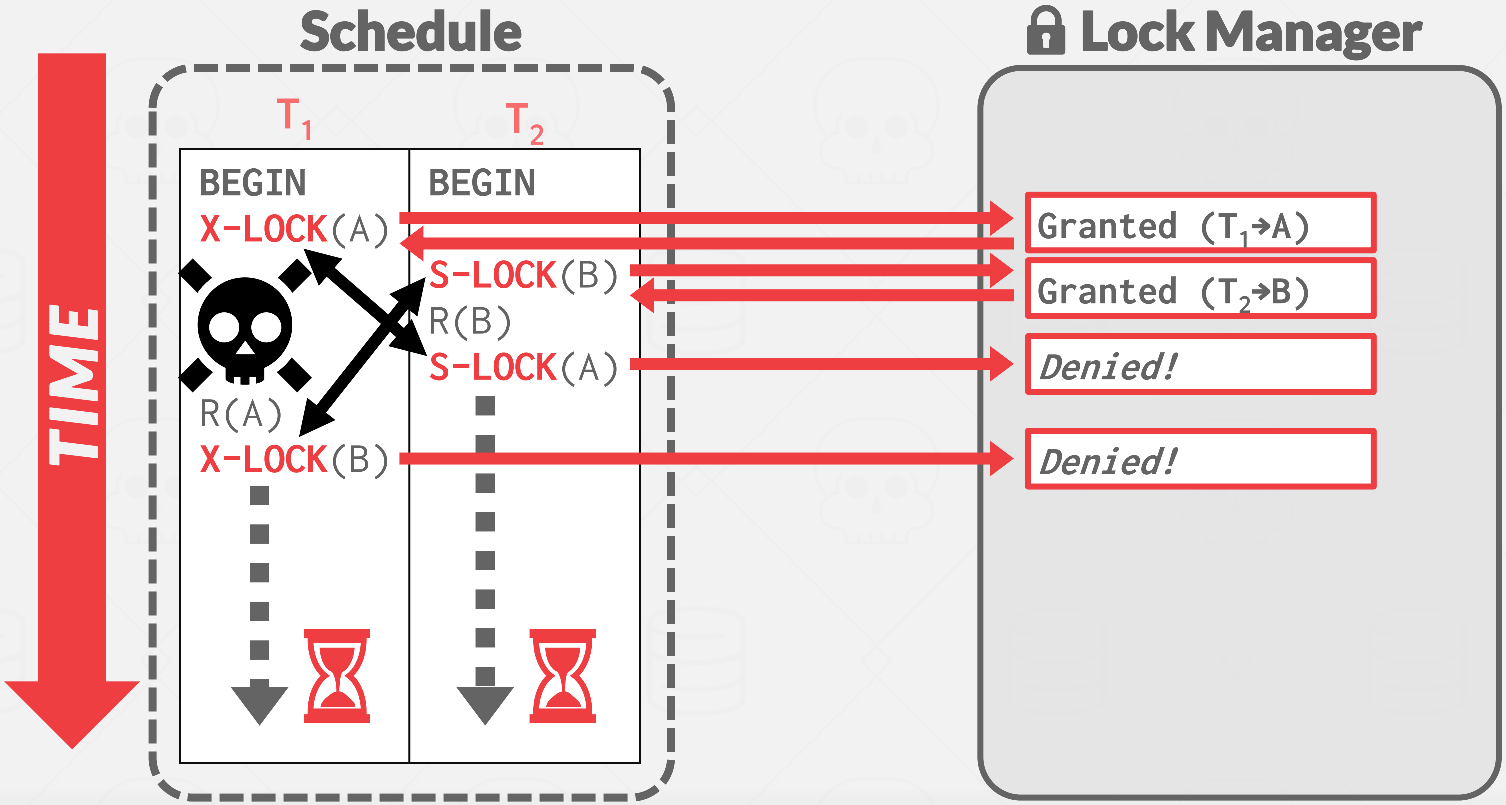
May still have "dirty reads".

→ Solution: **Strong Strict 2PL (aka Rigorous 2PL)**

May lead to deadlocks.

→ Solution: **Detection** or **Prevention**

IT JUST GOT REAL, SON



2PL DEADLOCKS

A **deadlock** is a cycle of transactions waiting for locks to be released by each other.

Two ways of dealing with deadlocks:
→ **Approach #1: Deadlock Detection**
→ **Approach #2: Deadlock Prevention**

DEADLOCK DETECTION

The DBMS creates a **waits-for** graph to keep track of what locks each txn is waiting to acquire:

→ Nodes are transactions
→ Edge from T_i to T_j if T_i is waiting for T_j to release a lock.

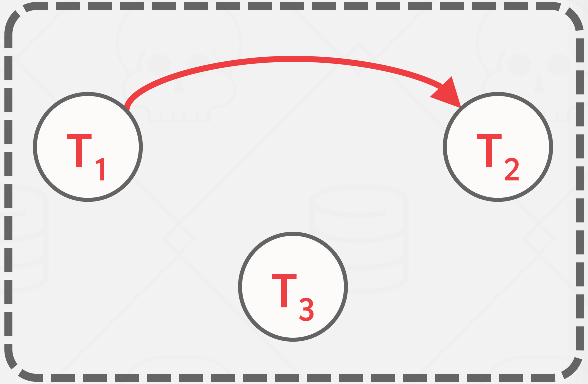
The system periodically checks for cycles in ***waits-for*** graph and then decides how to break it.

DEADLOCK DETECTION

Schedule

T_1	T_2	T_3
BEGIN	BEGIN	BEGIN
S-LOCK(A)		
	X-LOCK(B)	
		S-LOCK(C)
S-LOCK(B)		
	X-LOCK(C)	
		X-LOCK(A)

Waits-For Graph

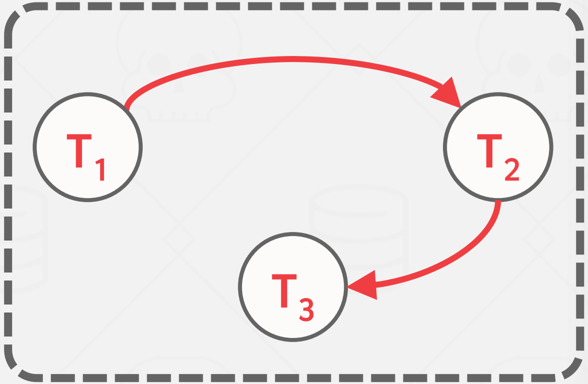


DEADLOCK DETECTION

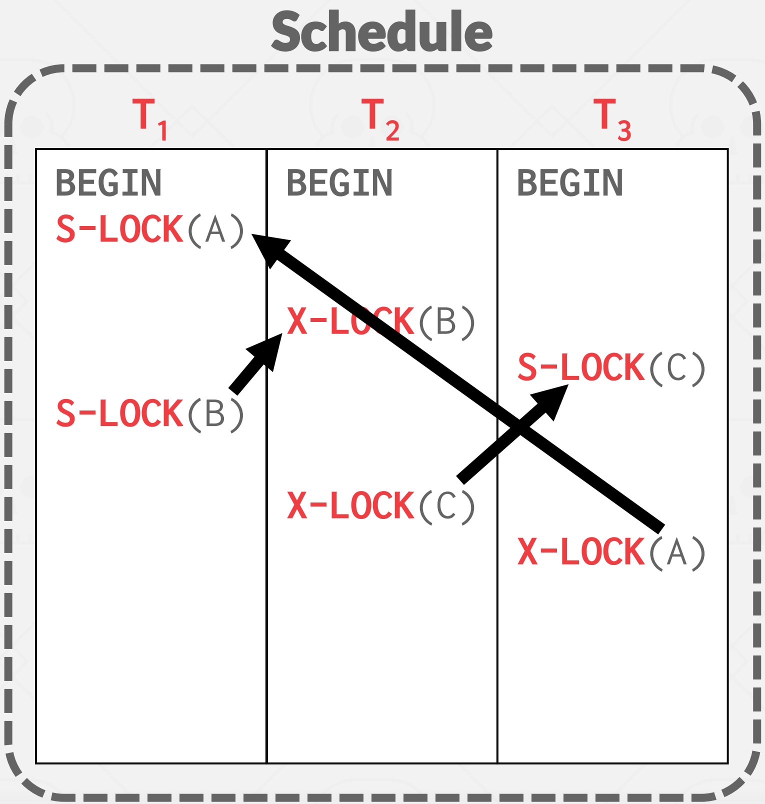
Schedule

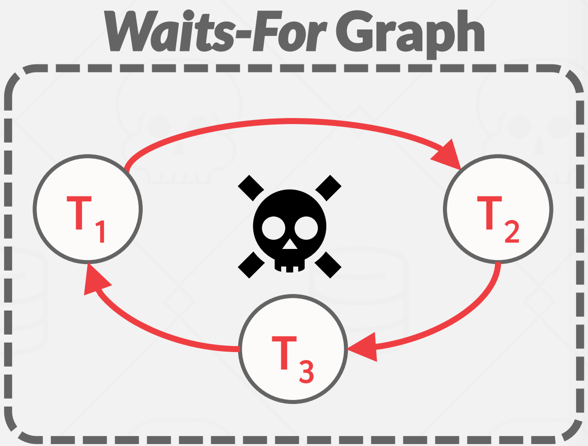
T_1	T_2	T_3
BEGIN	BEGIN	BEGIN
S-LOCK(A)		
	X-LOCK(B)	
		S-LOCK(C)
S-LOCK(B)		
	X-LOCK(C)	
		X-LOCK(A)

Waits-For Graph



DEADLOCK DETECTION





DEADLOCK HANDLING

When the DBMS detects a deadlock, it will select a "victim" txn to rollback to break the cycle.

The victim txn will either restart or abort (more common) depending on how it was invoked.

There is a trade-off between the frequency of checking for deadlocks and how long txns wait before deadlocks are broken.

DEADLOCK HANDLING: VICTIM SELECTION

Selecting the proper victim depends on a lot of different variables….

→ By age (lowest timestamp)
→ By progress (least/most queries executed)
→ By the # of items already locked
→ By the # of txns that we have to rollback with it

We also should consider the # of times a txn has been restarted in the past to prevent starvation.

DEADLOCK HANDLING: ROLLBACK LENGTH

After selecting a victim txn to abort, the DBMS can also decide on how far to rollback the txn's changes.

Approach #1: Completely

→ Rollback entire txn and tell the application it was aborted.

Approach #2: Partial (Savepoints)

→ DBMS rolls back a portion of a txn (to break deadlock) and then attempts to re-execute the undone queries.

DEADLOCK PREVENTION

When a txn tries to acquire a lock that is held by another txn, the DBMS kills one of them to prevent a deadlock.

This approach does not require a ***waits-for*** graph or detection algorithm.

DEADLOCK PREVENTION

Assign priorities based on timestamps:
→ Older Timestamp = Higher Priority (e.g., $T_1 > T_2$)

Wait-Die ("Old Waits for Young")
→ If *requesting txn* has higher priority than *holding txn*, then *requesting txn* waits for *holding txn*.
→ Otherwise *requesting txn* aborts.

Wound-Wait ("Young Waits for Old")
→ If *requesting txn* has higher priority than *holding txn*, then *holding txn* aborts and releases lock.
→ Otherwise *requesting txn* waits.

DEADLOCK PREVENTION

T_1	T_2
BEGIN	
	BEGIN
	X-LOCK(A)
	⋮
X-LOCK(A)	
⋮	

Wait-Die: T_1 waits

Wound-Wait: T_2 aborts

T_1	T_2
BEGIN	
X-LOCK(A)	
⋮	
	BEGIN
	X-LOCK(A)
	⋮

Wait-Die: T_2 aborts

Wound-Wait: T_2 waits

DEADLOCK PREVENTION

Why do these schemes guarantee no deadlocks?

Only one "type" of direction allowed when waiting for a lock.

When a txn restarts, what is its (new) priority?

Its original timestamp to prevent it from getting starved for resources like an old man at a corrupt senior center.

OBSERVATION

All these examples have a one-to-one mapping from database objects to locks.

If a txn wants to update one billion tuples, then it must acquire one billion locks.

Acquiring locks is a more expensive operation than acquiring a latch even if that lock is available.

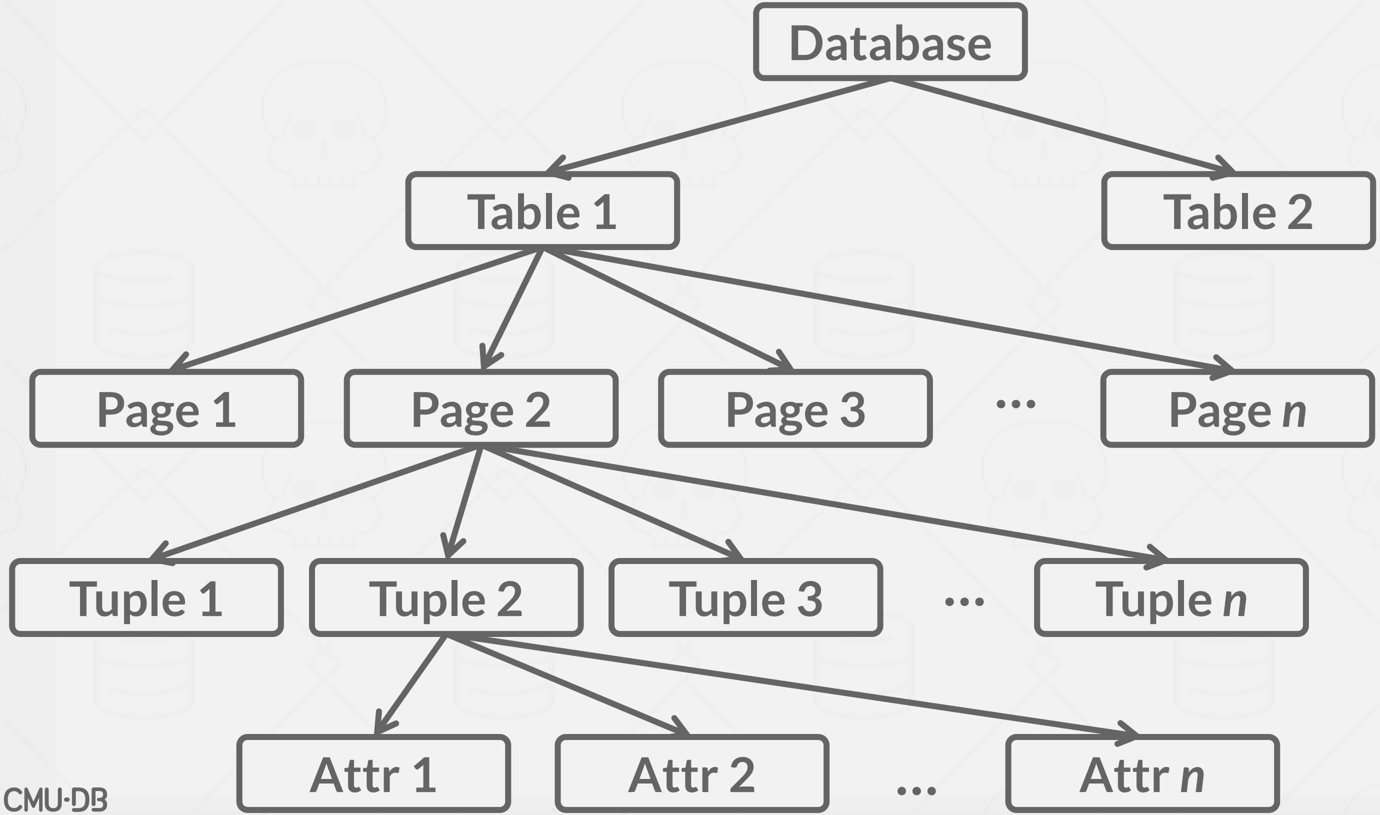
LOCK GRANULARITIES

When a txn wants to acquire a "lock", the DBMS can decide the granularity (i.e., scope) of that lock.
- → Attribute? Tuple? Page? Table?

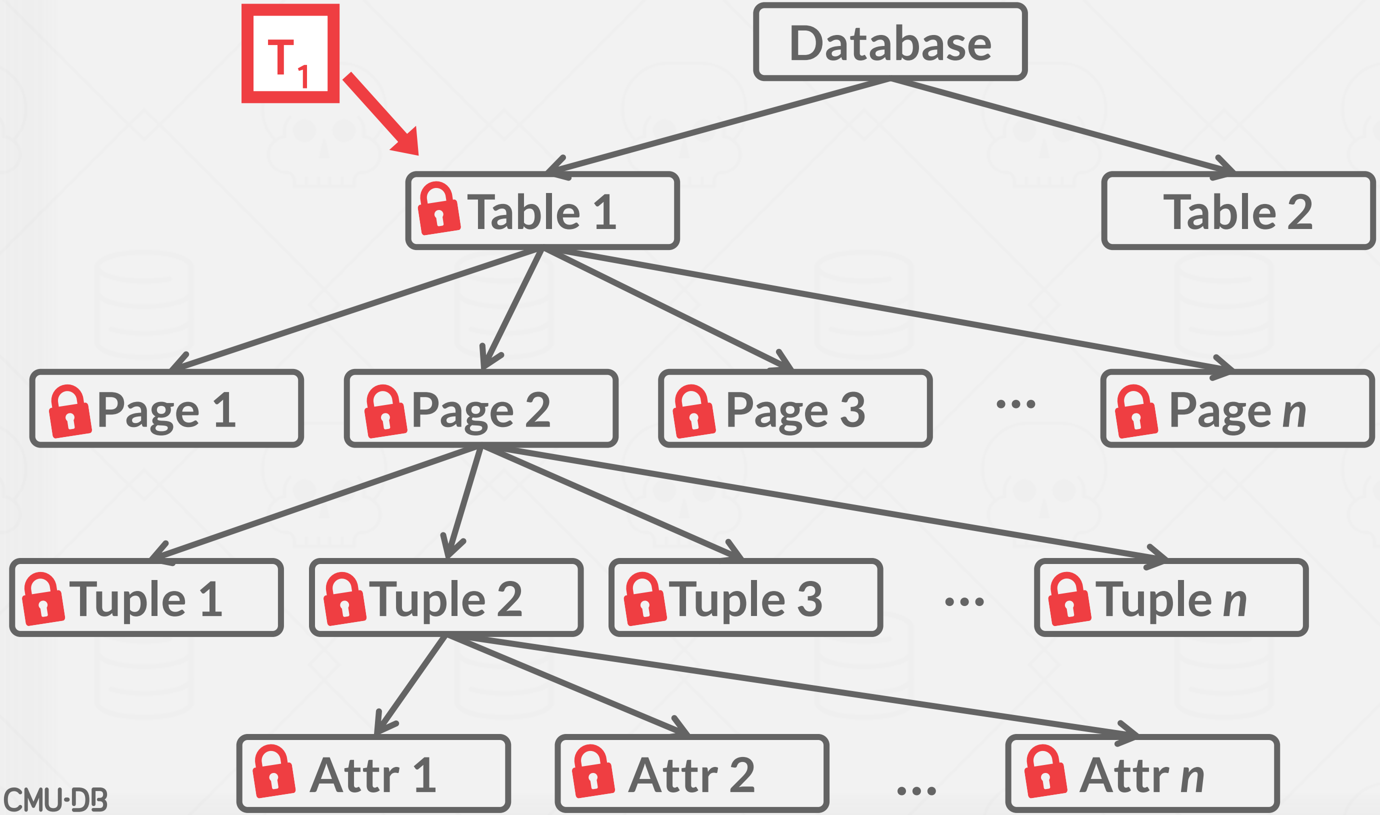
The DBMS should ideally obtain fewest number of locks that a txn needs.

Trade-off between parallelism versus overhead.
- → Fewer Locks, Larger Granularity vs. More Locks, Smaller Granularity.

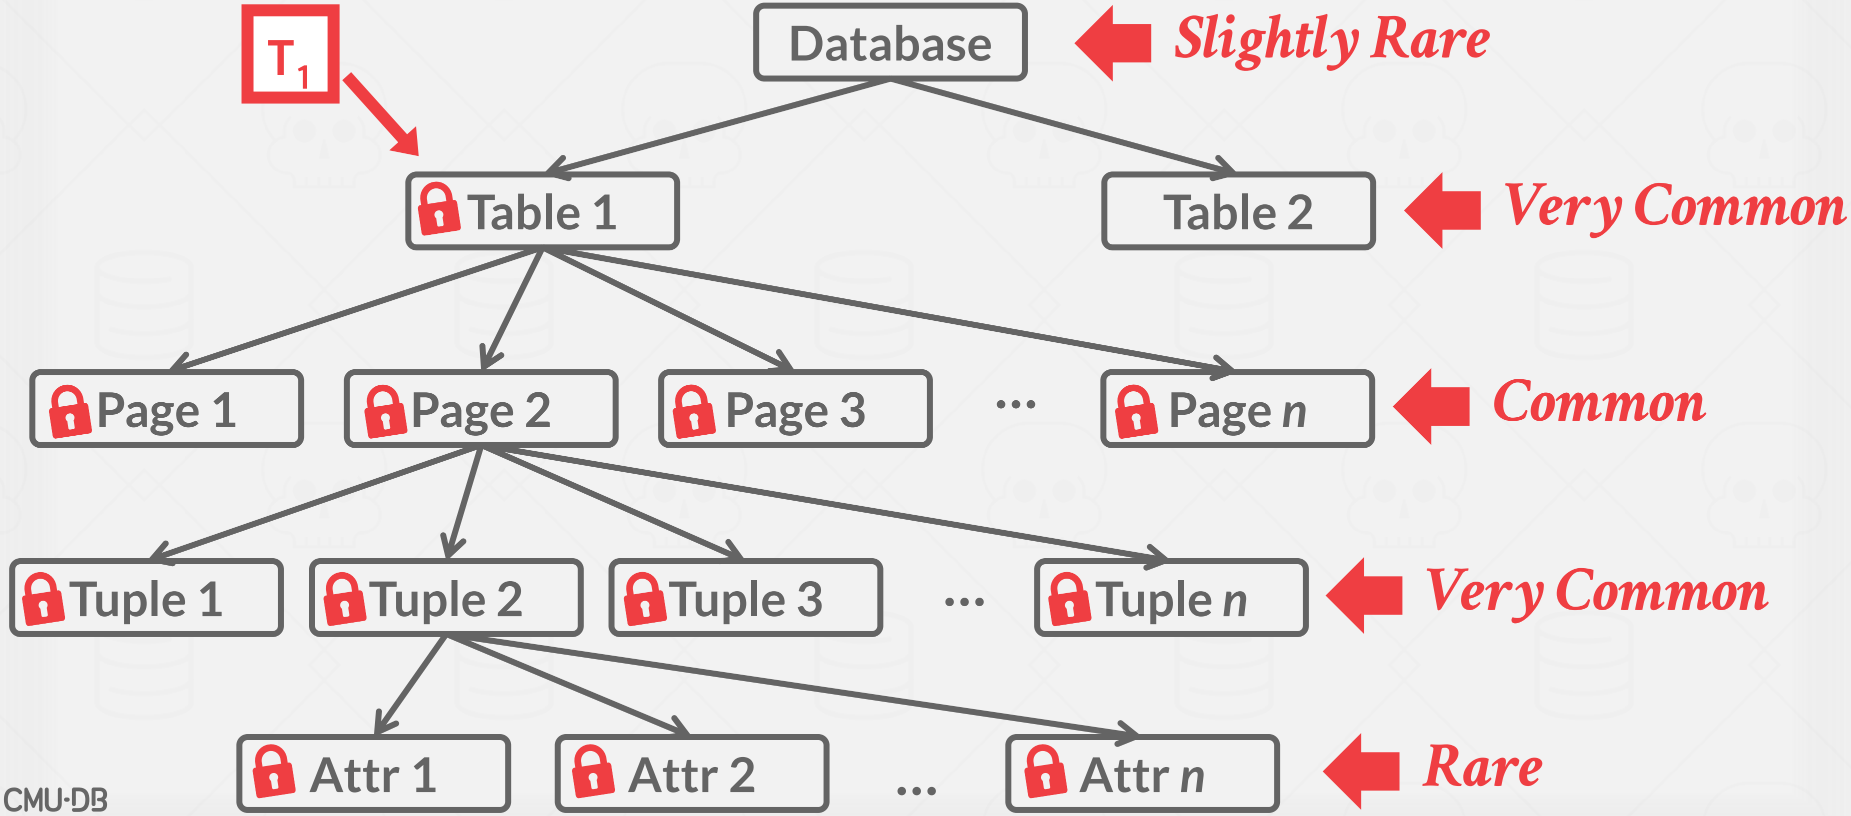
DATABASE LOCK HIERARCHY



DATABASE LOCK HIERARCHY



DATABASE LOCK HIERARCHY



INTENTION LOCKS

An **intention lock** allows a higher-level node to be locked in **shared** or **exclusive** mode without having to check all descendent nodes.

If a node is locked in an intention mode, then some txn is doing explicit locking at a lower level in the tree.

INTENTION LOCKS

Intention-Shared (IS)

→ Indicates explicit locking at lower level with shared locks.

Intention-Exclusive (IX)

→ Indicates explicit locking at lower level with exclusive locks.

Shared+Intention-Exclusive (SIX)

→ The subtree rooted by that node is locked explicitly in **shared** mode and explicit locking is being done at a lower level with **exclusive-mode** locks.

COMPATIBILITY MATRIX

T_2 Wants

T_1 Holds

	IS	IX	S	SIX	X
IS	✓	✓	✓	✓	×
IX	✓	✓	×	×	×
S	✓	×	✓	×	×
SIX	✓	×	×	×	×
X	×	×	×	×	×

LOCKING PROTOCOL

Each txn obtains appropriate lock at highest level of the database hierarchy.

To get **S** or **IS** lock on a node, the txn must hold at least **IS** on parent node.

To get **X**, **IX**, or **SIX** on a node, must hold at least **IX** on parent node.

EXAMPLE

T_1 – Get the balance of Andy's shady off-shore bank account.

T_2 – Increase DJ Mooshoo's account balance by 1%.

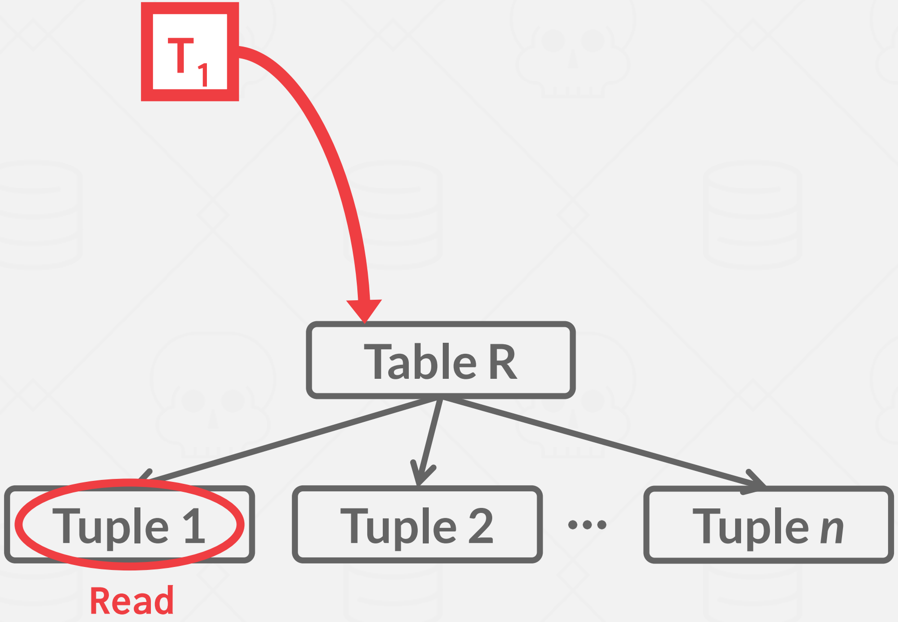
What locks should these txns obtain?

→ **Exclusive** + **Shared** for leaf nodes of lock tree.

→ Special **Intention** locks for higher levels.

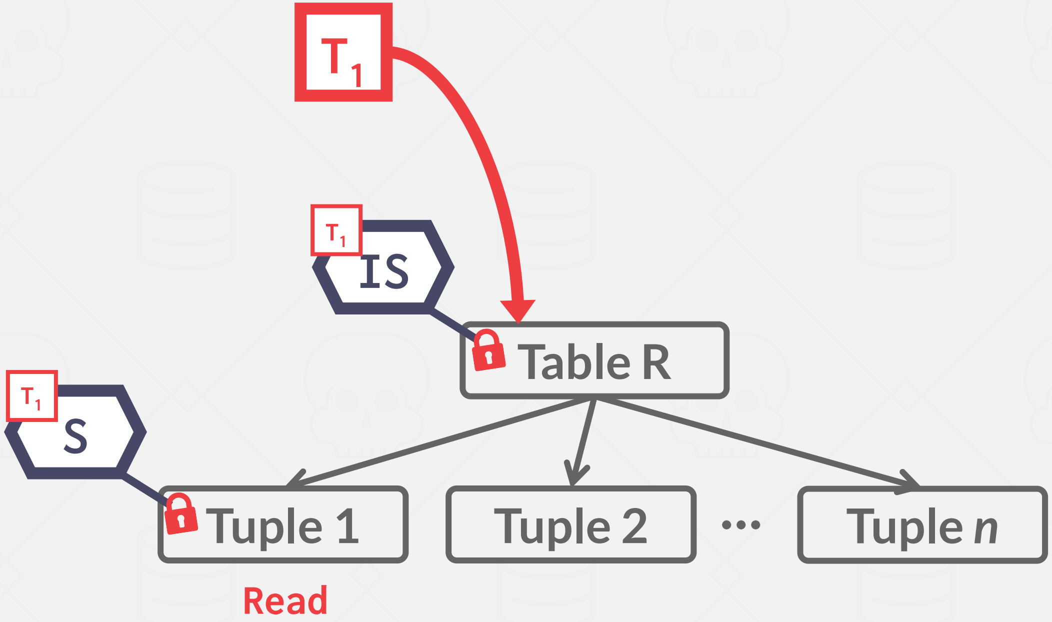
EXAMPLE – TWO-LEVEL HIERARCHY

Read Andy's record in **R**.



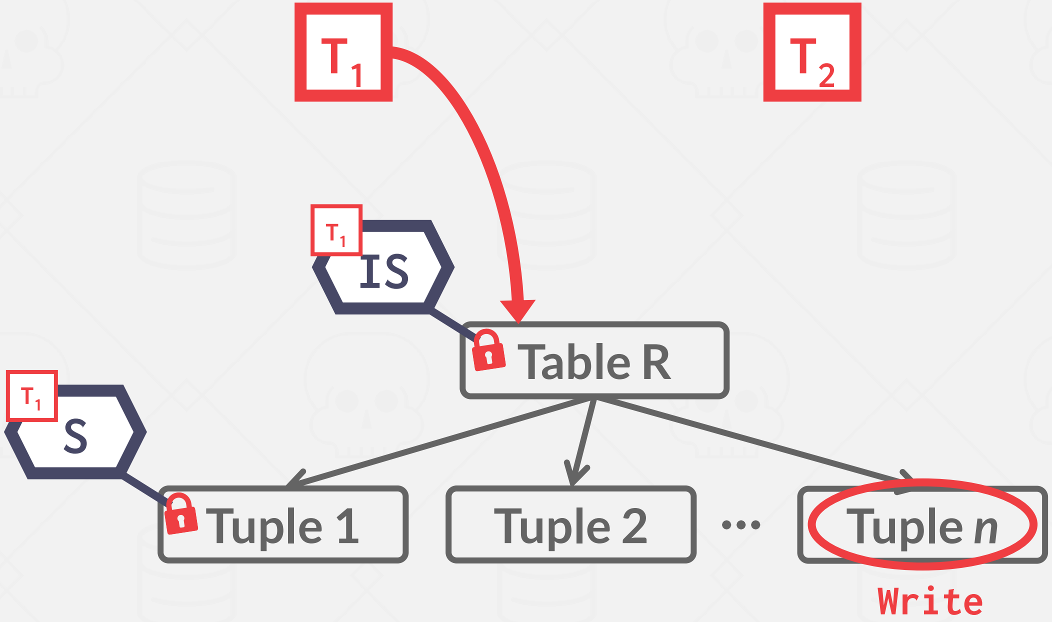
EXAMPLE – TWO-LEVEL HIERARCHY

Read Andy's record in **R**.



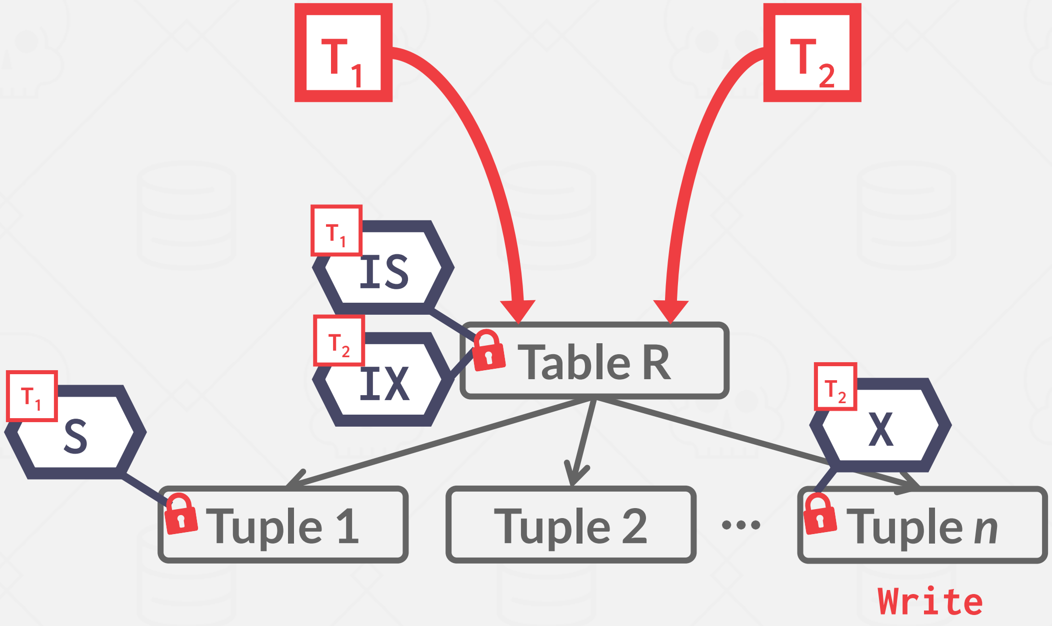
EXAMPLE – TWO-LEVEL HIERARCHY

Update Mooshoo's record in R.



EXAMPLE – TWO-LEVEL HIERARCHY

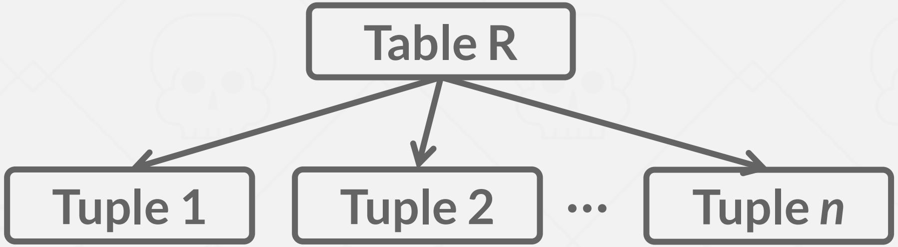
Update Mooshoo's record in **R**.



EXAMPLE – THREESOME

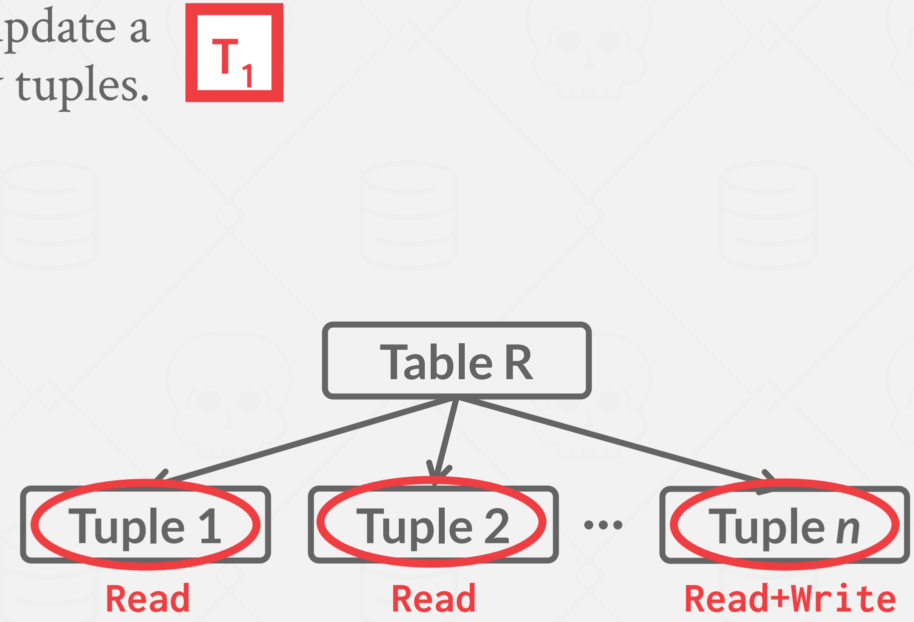
Assume three txns execute at same time:

→ T_1 – Scan R and update a few tuples.
→ T_2 – Read a single tuple in R.
→ T_3 – Scan all tuples in R.



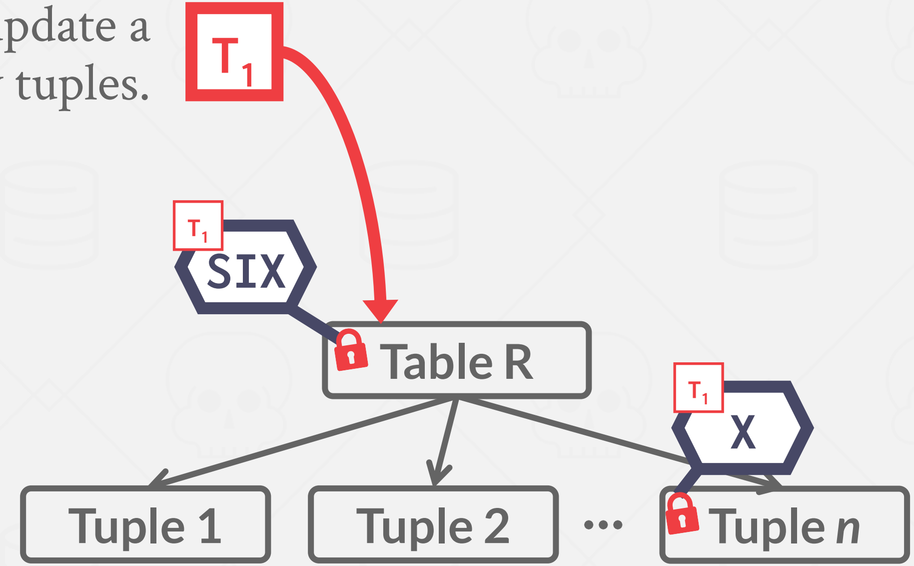
EXAMPLE – THREESOME

Scan **R** and update a few tuples.

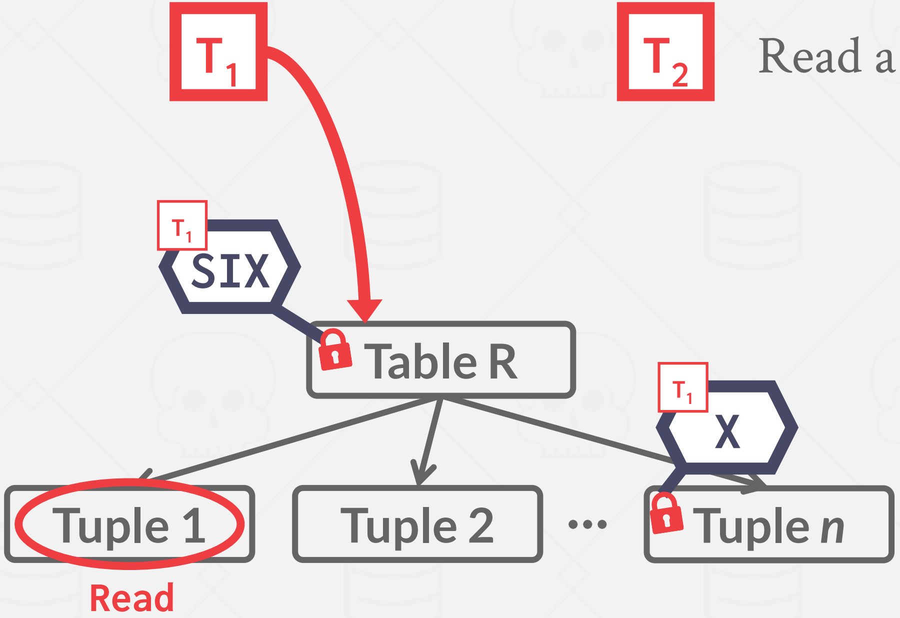


EXAMPLE – THREESOME

Scan **R** and update a few tuples.

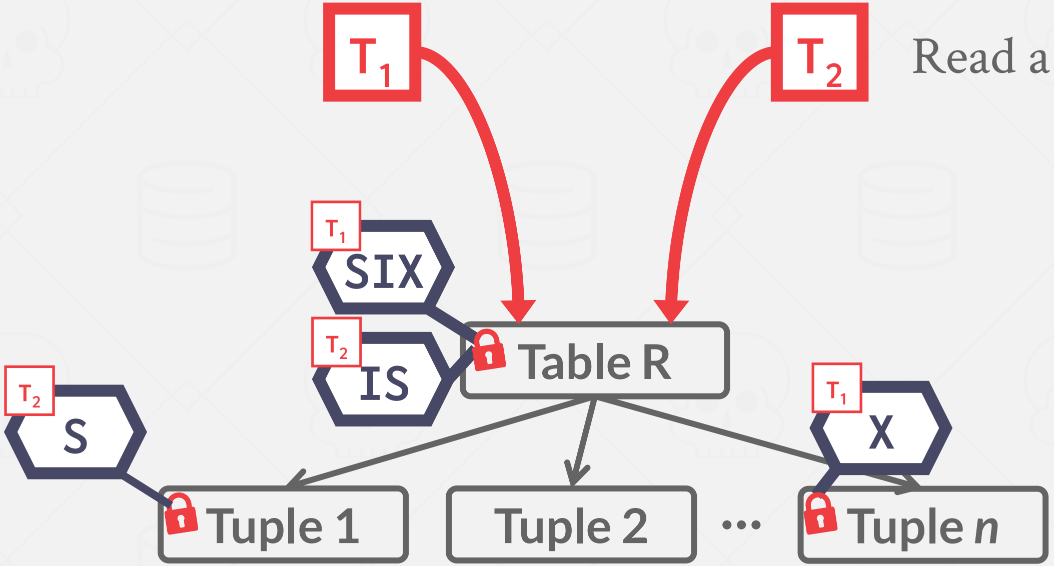


EXAMPLE – THREESOME



T2 Read a single tuple in **R**.

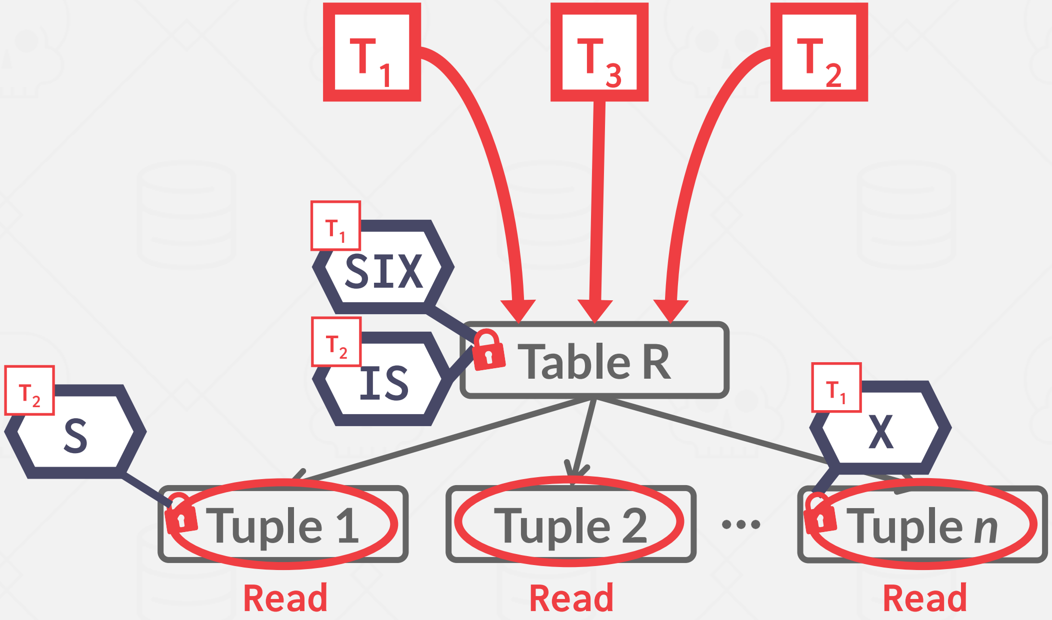
EXAMPLE – THREESOME



Read a single tuple in **R**.

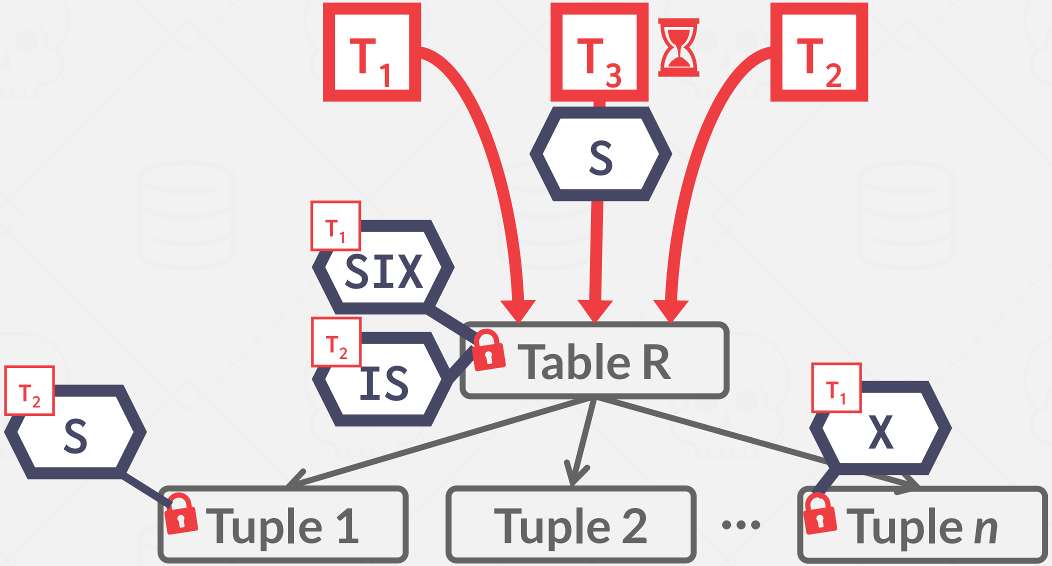
EXAMPLE – THREESOME

Scan all tuples in **R**.



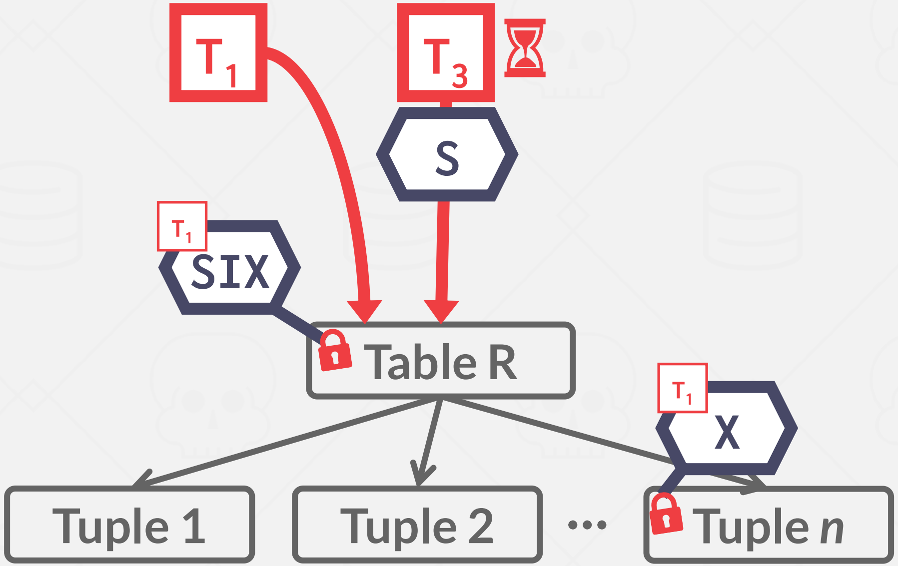
EXAMPLE – THREESOME

Scan all tuples in **R**.



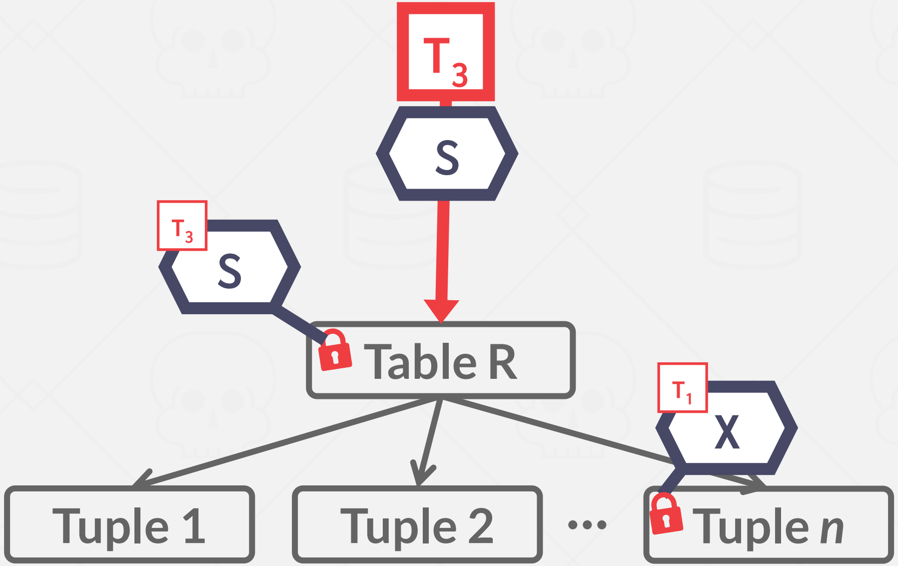
EXAMPLE – THREESOME

Scan all tuples in **R**.



EXAMPLE – THREESOME

Scan all tuples in **R**.



MULTIPLE LOCK GRANULARITIES

Hierarchical locks are useful in practice as each txn only needs a few locks.

Intention locks help improve concurrency:
→ **Intention-Shared (IS)**: Intent to get S lock(s) at finer granularity.
→ **Intention-Exclusive (IX)**: Intent to get X lock(s) at finer granularity.
→ **Shared+Intention-Exclusive (SIX)**: Like S and IX at the same time.

LOCK ESCALATION

The DBMS can automatically switch to coarser-grained locks when a txn acquires too many low-level locks.

This reduces the number of requests that the lock manager must process.

LOCKING IN PRACTICE

Applications typically don't acquire a txn's locks manually (i.e., explicit SQL commands).

Sometimes you need to provide the DBMS with hints to help it to improve concurrency.
→ Update a tuple after reading it.

Explicit locks are also useful when doing major changes to the database.

LOCK TABLE

Explicitly locks a table. Not part of the SQL standard.

→ Postgres/DB2/Oracle Modes: **SHARE**, **EXCLUSIVE**
→ MySQL Modes: **READ**, **WRITE**

```
LOCK TABLE <table> IN <mode> MODE;
```

PostgreSQL, ORACLE, IBM DB2

```
SELECT 1 FROM <table> WITH (TABLOCK, <mode>);
```

Microsoft SQL Server

```
LOCK TABLE <table> <mode>;
```

MySQL

SELECT...FOR UPDATE

Perform a select and then sets an exclusive lock on the matching tuples.

Can also set shared locks:

→ Postgres: **FOR SHARE**
→ MySQL: **LOCK IN SHARE MODE**

```
SELECT * FROM <table>
 WHERE <qualification> FOR UPDATE;
```

CONCLUSION

2PL is used in almost every DBMS.

Automatically generates correct interleaving:

→ Locks + protocol (2PL, SS2PL ...)
→ Deadlock detection + handling
→ Deadlock prevention
